#### REFACE.

have destroyed all my chemical Manuscripts. - A prospect. of returning health might have perfuaded me to purfue this delightful science; but I have now certainly done with it for ever; at least I have taken the most effectual step I could to wean myself from an attachment to it, for with the holy zeal of the Idolators of old, who had been addicted to curious arts - I have burnt my books. - I will have one

word more, however, at parting.

I have spent the best part of my life in this University; and have not been wholly incurious in observing, what I thought, were either excellencies or defects in our mode of Education. I mean not on this occasion to enlarge upon either, but simply to take the liberty of suggesting an hint, which has often engaged my attention. The hint respects - The Utility of an Academic Institution for instructing young Men of Rank and Fortune in the Elements of Agriculture; in the Principles of Commerce; and in the Knowledge of our Manufactures. toois bild a san in soubong

This kind of fludy would agreeably folicit, and might probably fecure, the Attention of that part of our Youth, which, in being exempted from the discipline of Scholastic Exercises; has abundant leisure for other pursuits; which, in being born to opulence, is (I will say) unhappily deprived of one of the strongest incentives to intellectual Exertion - narrowness of fortune; - it would prepare them for becoming at a proper age, intelligent Legislators of their Country; and it would inspire them with fuch a tafte for husbandry, as might conflitute the chief felicity of their future lives.

When the Treaty with Ireland was agitated last year in Parliament, the utility of a comprehensive knowledge of our commerce and manufactures was perfectly understood, both by those who possessed it, and by those who lamented their want of it. The commerce of Wool, Corn, Cotton, Hemp, Flax, Silk, Beer, Wine, Spirits, Salts, Sugar, Tar, Glass, Earthen Ware, Iron, Copper, I we may a likewish to notate and out or and tend,

## PREFACE.

Lead, Tin, &c. &c. are subjects of great importance to this Country, and it is humbly apprehended, that they are subjects also on which there are but few persons in either house of Parliament, who have had an opportunity of being properly instructed, during the course of their Education.

Davenant, Child, Postlethwayte, Anderson, and a great many other eminent writers on Trade and Commerce, would supply ample Materials for a System of Lectures, equally useful and entertaining. But as the attention of young men to abstract speculations is apt to slag, unless the subject be enlivened by a reference to the Senses, together with the commercial Account, I should think there might properly be given, both the Natural History, and the Chemical Analysis of the various objects which may

fall within the comprehension of such a plan.

- My own notion, indeed, of National Improvement, Security, and Happiness, tends not so much to the extending of our commerce, or the increasing the number of our manufacturers; as to the increaling of an hardy and, comparatively speaking, innocent Race of Feafants, by making Corn to grow on Millions of Acres of Land, where none has ever grown before. Let us but once have as many Britons in the Kingdom, as the well cultivated Lands of Great Britain are able to fultain, and we shall have little to regret in the loss of America; nothing to apprehend from the partitioning policy of all the continental Despots in Europe. Lenter not into the question concerning the population of the country; whether the Inhabitants of the Kingdom are more or fewer now than they were a century ago, cannot be conjectured with any great probability from the furveye of particular districts, but the real number may be known with little difficulty, whenever the Legislature hall be defirous of obtaining information on the Subthe Counties into Parishes, &c. an actual Enumeration Call Be wink

#### PREFACE.

of the Inhabitants might be made every ten years, by the Ministers and Church-wardens of the several Parishes, with as much certainty as the nature of the subject, considered in a political light, would require. But whatever may be the present number of the Inhabitants of Great Britain, there is no one who has thought upon the subject, but must admit, that were our Lands brought to their proper state of Cultivation, they would afford maintenance to twice as many as at prefent exist in the Country. In thus fixing the Basis of National Strength, in the improved Cultivation of our Lands, I am far from infinuating, that Manufactures and Agriculture cannot fubfift in an eminent degree of perfection together: on the contrary, I consider them as mutually subservient to each other, and am quite aware, that in the present state of the Finance of this Kingdom, our Commerce ought to be cherished with singular Indulgence. Nor shall we sufficiently avail ourselves of the inestimable Advantage of an Infular Situation, if we do not confider our Glory and our Safety as closely connected with the Number of our Seamen; and every child in Politics must know, that the number of our Seamen will ever be proportioned to the extent of our foreign, and domestic Commerce.

Of all the Amusements or Employments in which Country Gentlemen are engaged, that of superintending with intelligence the cultivation of a Farm, is one of the most useful to the Community, as well as to the Individual who applies himself to it. Great Improvements have been made in Agriculture within the last sifty years: there is a chaos of printed Information on the Subject, which wants to be digested into form, in order to be made generally useful. The several Agricultural Societies, which have been established by Gentlemen in different parts of the Kingdom, have done great Service; we owe to their endeavours and to the patriotic Exertions of one deserving Citizen \*, the present sourishing condition of our Husban-

#### PREFACE.

dry; but far more Gentlemen would, probably, have been induced to turn their thoughts that way, and all of them with better prospects of succeeding in their enquiries, had they, in their youth, been carefully instructed in the Principles of Vegetation, in the Chemical Qualities of Sails, and in the Natures and Uses of different Manures.—But I mean only to give a hint concerning an Institution, which I have no manner of expectation of seeing established, though I am fully persuaded it would be both a public benefit, and highly useful to that Class of Persons of whose Education I have

been fpeaking.

Young men of Fortune feel not the want of perfonal Merit during the short time which they spend at the Universities: they see Consequence and Respect, it is true, annexed in those Seminaries to Learning and Talents, but in the world they fee little respected but Wealth; and possessing that, or expecting to pollefs it from their Ancestors, they are easily allured by the Indolence which is natural to the Human Species, and by the Improvidence which is incident to their time of life, to thrink from the talk of acquiring accomplishments really honourable, really ufeful, and really their own. When they are called to the Legislation of their Country, or when they become mafters of families or are in any way fettled, as it is called, in the world, then they begin to be fenfible of the deficiencies of their personal Acquirements; they cease not to lament through life their own want of forelight in neglecting the Opportunities of Improvement which were offered to them in the Universities, or the Supiness of those who had the care of their Education, in not having stimulated them to the pursuit of useful studies. This is only the general account, for there are some to whom it is not applicable; and though it may not be in our power to counteract the indolent propensities of Nature, or to stem the torrent of fashionable levities, to which young Men, by a too early introduction into the world, are fatally exposed; yet it is our Duty to endeavour to augment the number of der er celiente at entater, per dette

#### PREFACE

those, who, at so green an Age, have learned to make a proper estimate of their futre uintellectual wants; and I know no method better adapted to essectionate this desirable End, than to propose to them entertaining Objects of Study, of which they may clearly perceive the immediate utility, in the application of the knowledge they attain, to the important purposes of Legislative Policy and Rural Occonomics.

I shall be told that there is not time for this : that even Classics Ethics, Mathematics, and, God forbid I should omit what is of infinitely more value than all the relt, the Institutes of Christianity, can be but superficially attended to during the few Months which these young Men reside in the Universities. I will not attempt to obviate this objection by making an invidious comparison between the Utility of Clasfics, Ethics, or Mathematics, and the branches of Study here hinted at ; I admit the force of it in its full extent. But I beg leave to alk, whose fault is it that young Men of Fortune flay not more years with us, and refide not amongst us more months in every year? Why must they, as soon as they have huddled through fix or eight Terms, be hurried abroad as if it were from an Apprehension, that they have Learned as much as an English University can teach them? Foreign Travel is of great use, when it is undertaken by Men who have learned to bring their passions under the control of Reason and Religion; who have had some Experience in Life, acquired fome Knowledge of the Manufactures, Policy, Revenues, and Refources of their own Country, the acquaintance of fuch Men will be fought after by perfous of Character and Learning in every country they pals through, they will be in a condition to receive, because they will possess the Ability of communicating Knowledge. But the prefent mode of fending young Meninto France and Italy tends only to fill Great Bris tain with dabblers in Virti, pretenders in Taffe, sciolists in Literature, and insidels in Religion.

But I perceive myself intensibly falling into what I mean to avoid—A discussion of the excellencies and defests of our System of Education.—Our excellencies are greater, perhaps,

#### PREFACE

than those who know us not are apt to suppose; and our defects are not fo much defects in our Institution (though I have never scrupled to profess an humble. Opinion that it might be amended) as in our Discipline; and the defects in our discipline; are not so properly our defects, as the defects of the Manners of the Age. If a young Man at seventeen be accustomed at home to have horses always at his command; to follow country diversions without restraint; to mix in long convivial familiarity with perfons of advanced age; to drink as much as he pleafes at his father's table; to hear improper connexions with the Sex spoken of in all companies as venial levities, and not to hear them feriously censured in any as Offences against Christian Morality; and if to all this he be fupplied, through a destructive indulgence, with sums of money excessive for his age, and far superior to his wants, can it be a matter of wonder that it is not in the power of an University to rectify the disorders of such a domestic Education? I have no intention to millead the Opinion of the world concerning us, nor to exculpate ourselves by criminating others. If we yield to the corruption of the Age, we yield as flowly as we can; and it is not, perhaps, possible for us, wholly to escape the Malignity of its Influence.

Cambridge, Feb. 9, 1786.

# ESSAY XXIX.

Delson of Frontal period of the death of the to the total

Of Lapis Calaminaris—Blende—Zinc—Brass.

The two principal ores of zinc are calamine and blende. The Arabic word climia, or, as it is pronounced by some, calimia, denotes the same substance which we call lapis calaminaris, calamine, or calamy; and hence Salmasius is of opinion, that they judge very preposterously who would derive calamine from calaem, an Indian word signifying, according to him, a species of metal resembling tin, which is dug near Malacca\*. With due deference to his authority,

\* Cadmia Arabibus dicitur climia, quod quidam pronuntiarunt ealimia, unde Græcis recentioribus عمره interdum scribitur, unde nostris Gallis calamina et lapis calaminaris: quam vocem quidam præpostere deducunt ab Indico calaem, quod metalli genus est stanno simile haud longe ex malacca erui solitum. Salm. de Homony. Hy. Iat. C. CXXII.

rity. I would observe, that Indian calgem is not like tin. Many years ago the Dutch took a Portuguese vessel which was laden with calaem\*, and from all the experiments which were made upon that fubstance, it appeared to be zinc, or that metallic fubstance, which we in Europe have very lately learned the method of extracting from calamine. Both calamine and zine have the property of changing copper to a yellow colour; and this is the most distinguishing property of them both; it is that for which they are both fought after in commerce, and as climia and calaem have the fame radical letters, and denote in the Arabic and Indian languages, two fubstances which agree in one of their most characteristic properties, I leave it to others to determine whether they are not the same word, and in which of the two languages that word was originally formed.-The other ore of zinc is called by the Germans blende; from its blinding, or milleading appearance; it looking like an ore of lead, but yielding (as was formerly thought) no metallic fubstance of any kind +. A particular fort of lead ore has been called by Pliny, galena, from a Greek word fignifying to shine, because it is composed of shining particles; our potters ore and the Derbyshire lead ore is of this fort; blende much refembles galena, but yielding no lead, it has been called false or pseudogalena, or mock lead; our English miners have called it black jack, and that is the name by which it is known to the makers of brass. Black jack resembles lead ore so much, that the miners fometimes succeed in felling, to inexpeienced Theoler latem to existent a min of fmelters,

<sup>\*</sup> Savotus de Num. Ant. P. II. C. XIV.

Pseudo-galena nomen suum exinde acquisivit, quod saciem quasi mineræ plumbeæ præ se serat, sed mentiatur, cum id revera non contineat, quod externo aspectu pollicetur. Germanis appellatur blende a blenden, quia, cum salso speciem mineræ sarurninæ præ se sert, exinde oculos sascinet, vel iis imponat. Pott de Pseudo-galena, p. 106.—They have in Staffordshire a sort of iron, which they call blende-metal, of which they make nails, hammers, &c. Plot's Staf.

finelters, black jack instead of lead ore; I have heard of the fraud being carried to so great an extent in Derbyshire, that from a ton of ore there was not obtained above a few ounces of lead; though a ton of unadulterated lead ore yields in Derbyshire, at an average, 14 or 15 hundred weight of lead.

Calamine is found in most parts of Europe; we have great plenty of it in Somerfetsbire, Flintsbire, Derbysbire, and in many other parts of England. It is scarcely to be distinguished by its appearance from some forts of limestone; for it has none of the metallic lustre usually appertaining to ores; it differs, however, by its weight from every fort of stone, it being, bulk for bulk, near twice as heavy as either flint, or limestone. Before the reign of Elizabeth, this mineral was held in very little estimation in Great Britain; and even at so late a period as towards the end of the last century, it was commonly carried out of the kingdom as ballaft, by the ships which traded to foreign parts, especially to Holland . Its use is now as perfectly understood in England, as in any part of the world; and as we have greater. plenty of calamine, and that of a better fort, than most other nations have, there is no fear of our lofing the advantages in this article of trade, which we are now possessed of.

Great quantities of calamine have of late years been dug in Derbyshire, on a spot called Bonfale Moor, in the neighbourhood of Matlock. A bed of iron stone, about four feet in thickness, lies over the calamine; and the calamine is much mixed not only with this iron stone, but with cawk, lead ore, and limestone. The calamine miners never wish to meet with lead ore; they say, that it eats up the calamine; and the lead miners in return never wish to meet with calamine in a rich vein of lead

bloow

<sup>\*</sup> Essay on Metal: words by Sir J. Pettus; and Phil. Trans, for 1694.

ore, fince they are persuaded that it injures the quality of the ore. It would be too much to infer from these observations of the miners, that one of these substances arises from the natural decomposition of the other. Juxtaposition of substances in the bowels of the earth is no certain proof of their being derived from each other; for no one will contend that chert is derived from the limestone in which it is bedded; or sint and pyrites from the chalk in which they are found; yet when a great variety of substances are found mixed together in the same little lump, the mind cannot help conjecturing that a more improved state of mineralogy will shew some connexion in their origin. I have often seen calamine, and black jack, and lead ore—and cawk, black jack, and lead ore—and cawk, black jack, and lead ore—and cawk, black jack, and lead ore—bedded together in the same piece of spar.

The calamine annually raised in Derbyshire, amounts to about fifteen hundred tons. Sixty years ago, (as I was informed by an intelligent dealer in calamine, whose father was one of the first who dug it in that county,) they did not raise forty tons in a year. The Derby shire calamine does not bear fo good a price as that which is gotten about Mendip in Somerfetsbire; the former being fold for about forty shillings, and the latter for fixtyfive or feventy shillings a ton before dressing: when thoroughly dreffed, the Derbyshire calamine may be bought for about fix guineas, and the other for eight pounds a ton. This dreffing of the calamine confifts, principally, in picking out all the pieces of lead ore, limestone, iron stone, cawk, and other heterogeneous substances which are mixed with it, when it is first dug from the mine; this picked calamine is then calcined in proper furnaces, and by calcination it loses between a third and a fourth part of its weight.

The substance which is lost during the calcination of the calamine is not either sulphur or arsenic, or any thing which can be collected by the sides of an horizontal chimney, as is the case in some sorts of copper and lead ores; hence it

would

would be quite unferviceable to roast calamine in a furnace with such a chimney. The truth of this remark will ap-

pear from the following experiment.

I took 120 grains of the best Derbysbire calamine, and diffolved them in a diluted vitriolic acid; the folution was made in a Florence flask, and the weight of the acid and flask was taken before the folution commenced. About twenty hours after the folution had been finished, I weighed the flask and its contents, and found that there had been a loss of 40 grains, or one third the weight of the calamine; about a grain of earth remained at the bottom undissolved. If the same quantity of the purest limestone had been dissolved in the same way, there would have been a loss of weight equal to 54 grains; the substance which is separated from calamine by calcination, or by solution in an acid, is of the fame nature with that which is separable from limestone by the same processes-fixed air. This air having the property of changing the blue colour of vegetables to a red, as well as many other properties of an acid, and being contained in great abundance in the atmosphere, has been called by fome-aerial acid-and by others from its constituting nine parts in twenty of chalk and other calcareous earths-chalky acid-and from its being destructive of flame and animal life, fome have denominated itmephitic air. The weight which was thus lost by dissolving the Derbyshire calamine in an acid, corresponds sufficiently with that which the workmen observe to be lost during the calcination of that mineral; fo that these processes, as was observed in a former Essay concerning similar ones when applied to calcareous earths, mutually confirm each other. The parties with which he to the street and the first

Bergman observes, that 100 grains of Flintsbire calamine lost by calcination 34 grains\*; now this quantity corresponds, as much as can be expected, in things of this fort,

fort, with the loss which I observed during the folution of 120 grains of the Derby bire calamine; for if I had diffolved only 100 grains, the loss would have been 331. The fame author, however, remarks that 100 grains of Flintshire calamine, when dissolved in an acid, gave only 28 grains of air; and he thinks that 6 grains of water are contained in every 100 grains of that fort of calamine; for he takes the difference which he observed, between the weight of air obtained by folution, and the loss of weight fultained during the calcination of 100 grains of calamine, to be owing to the water which is dispersed during the process of calcination +. Fontana obtained 190 grains of fixed air from 576 grains of Romerfetsbire calamine; according to the fame proportion, had he used only 100 grains, he would have had 33 grains of fixed air, instead of the 28 which Bergman got from the Flintshire calamine; I say inflead of the 28, for I am inclined to think, that the Derbyshire, Flintshire, and Somersetshire calamines do not differ much from each other in the quantity of air which they contain; but that the apparent difference, in the analyses of them here mentioned, proceeds rather from the mode of operating

flances, containing fixed air, particularly calcureous earths. He found that 100 grains of transparent calcureous spar gave, by solution in an acid, 34 grains of fixed air, and lost by calcination 45 grains; the difference, 11 grains, he says is water, which, though expelled by the fire, remains mixed with the acid, and hence 100 grains of such spar contain 55 grains of lime, 34 grains of fixed air and 11 grains of water. I have a little dissipation of sixed air and 11 grains of water. I have a little dissipation of these bodies, I do not absolutely deny the justice of it, but I hesitate concerning it; because from experiments which I made with all the care I could, and which are mentioned in the Essay on calcureous earths, I found that sine transparent spar, very white marble, &c. lost, as nearly as could be estimated, the same weight, whether they were dissolved in an acid, or calcined in a strong fire.

- March State of The

operating, than from the fubstances themselves. But though future experience should prove, that very pure pieces of the calamines we are speaking of do exactly agree as to the quantity of air contained in them, it will not follow, that the calamines, as prepared for sale by the miners of burners, will be similar to each other in all their properties; since they may be mixed with different quantities and with different sorts of heterogeneous substances; from which it may be impossible wholly to free them.

The reader must not conclude, from what has been said, that all sorts of calamine lose one third of their weight by calcination, or afford fixed air by solution in acids. Bergman analized some calamine from Hungary, and he found noo grains of it to consist of 84 grains of the earth of zinc, of the earth of iron, 1 of clay, and 12 of silicious earth; no mention is made of water in this analysis.

In the great works, where calamine is prepared for the brake makers, after it has been properly calcined, by which process, as has been observed, it loses between a third and a fourth part of its weight; it is again carefully picked, the heterogeneous parts having been rendered more discernable by the action of the fire; it is then ground to a fine powder afterwards it is washed in a gentle rill of water, in order to free it, as much as possible, from the earthly partieles with which it may be mixed; for thefe, being twice as light as the particles of the calamine, are earried off from it by the water; it is then made up for fale. A ton of the erude Derbyshire calamine, as dug from the mine, is reduced, by the various processes it undergoes before it becomes falcable, to about twelve hundred weight; and hence it has loft & parts in 20. Of the 8 hundred weight thus loft in a ton, 63 may be efteemed fixed air, the remaining part, amounting to 11, confifts of fome impurities which have been picked out or washed away, and of some portion Vol. IL

. Wielelv :

I believe,

<sup>\*</sup> Berg. C hem. Eff. Vol. II. p. 325.

of the metallic part of the calamine, which is indamed and driven off during the calcination; for I cannot agree with Wallerius in supposing that the ores of zinc lose no part of their fubstance during the ordinary process of calcination; the blue flame which is visible in the furnace where the calamine is calcined, and the injury which the calamine fuftains from being calcined with too strong a fire, are proofs to the contrary. It would be possible to use calamine for the purpose of making brass without calcining it; for the fixed air would be diffipated by the heat applied in making the brafs. But as in using a ton of uncalcined calamine, there would be between fix and feven hundred weight put into the brafs pots, which would be of no manner of use in the operation, it is a wifer method to get rid of fo large a quantity of unferviceable matter; especially as the carriage of fix or feven hundred weight to the diffance to which the prepared calamine is fent for the making of brass. would coft more than the calcination of a ton of it process, as has been observed, it toles between to shuoms

There are many forts of blende or black jack, which differ from each other not only in their external appearance, but in their internal constitution. In general they contain zinc and fulphur, united together by the intervention of iron, or of calcareous earth: and they must be previously freed from their fulpher by calcination, before they can be applied to the making of brafs. Some forts of black jack lofe one fourth, other about one fixth of their weight by calcination; what is thus dispersed consists principally of fulphur with a little water; what remains confifts of a large portion of zinc earth, mixed with one or more of the following fubstances, viz. iron, lead, copper, clay and flint. Black jack is found in North Wales, in Cornwall, and in Derby fire; and probably it may be mer with in many other parts of Great Britain. It has for many years been used, as well as calamine, for the making of brafs at Briftol, and,

Charles II to Contract of

I believe, it was first used there under a patent; but so little was this application of it known in other parts of the kingdom, that in the year 1777, they begged me in Derbyshire (where they had a little before that time begun to fave it) not to divulge the purpose to which it might be applied.

It has not been long well understood, that either calamine or black jack contained any metallic fubstance. Matthiolus, Agricola, Caneparius, and other expert and more ancient metallurgifts, esteemed calamine to be a mineral, in. which there was no metallic fubstance. Their mistake on this fubject was very excufeable; for the metallic fubstance contained in calamine, being of a volatile and combustible nature, it is confumed or diffipated by the ordinary processes in which metals are extracted from their ores. Most ores require to be fluxed in contact with charcoal, or fome other fubitance containing phlogiston, before they will yield their metals; and when they are thus fluxed, the metal, instead of being dispersed in vapour, is collected into a mass at the bottom of the veffel, or furnace, in which the operation is performed. Calamine, in like manner, must be united to phlogiston, before its metallic part, which is called zinc, will be properly formed; but as foon as it is formed, it flies off in vapour, and taking fire burns with a vivid flame. This phenomenon is easily made apparent, by mixing calamine in powder and charcoal dust together, and exposing the mixture to a melting heat, for a flame will iffue from it very different from what charcoal alone would yield; no mass of any metallic substance will be found at the bottom of the veffel; but in the place where the experiment is made, there will be feen many white flocks floating in the air; these slocks are the ashes of the metallic fubstance of the calamine, they are called flowers of zinc, lana philosophorum, nihil album, and by other fanciful Ff 2 names.

Opuf is Marg. Vol. I. p. 74.

<sup>\*</sup> Canep. de Atram, p. 12-21.

names. The metallic vapour which rifes from a mixture of calamine and charcoal, when exposed to a proper degree of heat, and the firing of which causes the slame which may be observed, cannot burn without air; and it was on this principle that Marggraf proceeded, when he extracted zinc from calamine by distillation in close vessels in 1746. He put 8 parts of powdered calamine, and 1 of powdered charcoal, well mixed together, into an earthen retort; and having sitted a receiver, with a little water in it, to the neck of the retort, in such a manner as to exclude the air, he exposed the mixture to a strong heat; there rose into the neck of the retort, where it was condensed, the metallic vapour of the calamine. By this method he ascertained the quantity of zinc contained in different sorts of calamine.

He tried some stones from Aix-la-Chapelle, which had been given him for calamine, in the same way, but obtained no zinc from them, and thence he concludes, that they were not calamine stones; for every stone, says he, which being mixed with charcoal, and exposed in close vessels to the action of a violent sire, does not yield zinc; or which in an open sire does not with copper and charcoal produce brass, ought not to be considered as a calamine stone. Henckel had long before given a similar definition of zinc, when he observed that it was the only substance in nature which had the quality of giving copper a yellow colour.

<sup>\*</sup> Opuf. de Marg. Vol. I. p. 94. † Pyrito French Trans. p. 248.

Pott wrote a differtation on zinc in 1741, in which he enters into the history of the discovery of this semi-metal; Bergman has availed himself of all that Pott knew on the fubject, and has added feveral things of his own; I cannot compress the matter into a less compass than he has done. "The femi-metal, which at prefent is called zinc, was not known fo much as by name to the ancient Greeks and Arabians. The name which it bears at present first occurs in Theophrastus Paracelsus, but no one as yet has been able to discover the origin of this appellation. A. G. Agricolo calls it contrefeyn +; Boyle, fpeltrum 1: by others it is denominated spiauter, and Indian tin 1. Albertus Magnus, more properly called Bolftadt, who died in 1280 ¶, is the first who makes express mention of this semi-metal. He calls it golden marcafite, afferts that it approaches to a metallic nature, and relates that it is inflammable. However as zinc is white, the name of golden marcafite is not very proper; it would therefore appear probable, that it derives that name from the golden colour which it communicates to copper, had not Albertus expressly faid, that copper united with golden marcafite becomes white; but he has probably either mifunderstood or misrepresented what he had heard related by others. It may also happen, that zinc was formerly thought to contain gold. J. Matthesius & in 1562, mentioned a white and a red zinc; but the yellowness and redness are only to be understood of the ores. Hollandus, Basil Valentine, Aldrovandus, Cæsius, Cæsalpinus, Fallopius and Schroeder, observe a profound silence on that head .\*. The eastern Indians have long fince been in possession of the method of F.f 3 extracting

tracting pure zinc from the ore; at least in the course of the last century this metal was brought from thence to Europe. Jungius mentions the importation of zinc from India, in 1647 #; a metal of this kind, under the name of tutenag, is still brought from thence, which must be carefully diffinguished from the compound metal of that name. G. E. Van Lohneiss tells us, in 1617, that a long time before zinc had been collected by fusion at Goslar +. It has been long usual to form orichalcum from the ores of zinc by the addition of copper; but it does not yet appear at what time this art was invented. Pliny makes mention of the orichalcum, as also of three species of Corinthian vases, one of which is yellow, and of the nature of gold to Erasmus Ebner, of Noremberg, in the year 1550, was the first who nsed the cadmia of Goslar for this purpose. In the year 1721, Henckel indeed mentioned that zinc might be obtained from lapis calaminaris by means of phlogiston, but he conceals the method 5. The celebrated Anton. Van Swab, in 1742, extracted it from the ores by distillation, at Westerwick in Dalecarlia J. It was determined to found a work for the purpose of extracting larger quantities of this semi-metal: but afterwards, for various reasons, this project was laid It may all a largen, that gine was formeris thear

Pyritologia—Henckel's words deserve to be quoted, I take them from the French translation of the Pyritologia, p. 295.—On fait, par exemple, avec la calamine non-seulement du fer, il est vrai en petite quantité, mais encore une tres-grande quantite de zinc, que l' on obtient non-seulement en lui présentant le corps avec lequel il peut s' incorporer, c' est-a-dire le cuivre qui est son aiman, mais encore ce demi-metal fe montre simplement par l' addition d' une matiere graffe qui metallise; il faut seulement pour eviter que ce phénix ne se reduise en cendre, empêcher qu'il ne se brale, et observer le tems et les circonstances.

¶ Elogium magni hujus Metallurgi coram R. Acad. Stock recitatum.

aside; therefore the illustrious Marggraf, not knowing what had been done by the Swedish mineralogists, in the year 1746, published a method of performing this operation, which he had discovered himself \*, It is not known how zinc is extracted in China. A certain Englishman, who several years ago took a voyage to that country for the purpole. of learning the art, returned fafely home, indeed, and appears to have been sufficiently instructed in the secret, but he carefully. concealed it. We find afterwards that a manufactory had been established at Bristol, where zinc is said to be obtained by distillation per descensum. We have already seen that it had been before obtained in Sweden by distillation per afcenfum, which afterwards was effected in larger quantity by Mess, Cronstedt and Riman, two very celebrated mineralogists and metallurgists. The difficulties occasioned by the volatile and combustible nature of this metal for a clong time retarded the knowledge of the ores containing it; nor is that wonderful, as being of a metallic form, it has even to our times been confidered as composed of two or three ingredients. Albertus Magnus thinks iron an ingredient; Paracelfus called it a spurious son of copper; Lemery holds it to be a species of bismuth; Glauber, and many alchemists, consider it merely as an immature folar sulphur; Homberg, as a mixture of tin and iron; Kunckel, as a coagulated mercury; Schluter, as tin made brittle by fulphur, &c.—The celebrated Brandt, in 1735, shewed that blende contained zinc +; and foon after D. Swab actually extracted it from the Bolognian Pseudogalena, which possesses a metallic splendor. The Baron Funch, in 1744, determined. the presence of zinc in pseudo-galena from the slame and the flowers +, and in 1746, Mr. Marggraf fet the matter out of is one color, smills the base eapsi, et augmentem ponderis duob

Bergman in this history of the discovery of the method of extracting zine from calamine, wholly omits the mention

of Dr. Ifaac Lawfon; of whom Pott, in his Effay on Zinc, fpeaks very respectfully, acquainting us that he really obtained fome grains of that femi-metal from calamine. So that though Henckel was the first, Lawfon was, probably, the fecond person in Europe who procured zinc from calamine; whether he was the Englishman who, according to Bergman, went to China to discover the method of doing it, is what I have not been able to learn with certainty. Our English writers who have touched on this subject, speak in high terms of Lawfon, I suppose from their personal knowledge of him, for they do not refer to any written account . Thus Dr. Pryce fays, " + the late Dr. I. Lawfon observing that the flowers of lapis calaminaris were the fame as those of zinc, and that its effects on copper were also the fame with that femi-metal, never remitted his endeavours till he found the method of feparating pure zinc from that ore." And Dr. Campbell, in his Survey of Britain, is still more particular: " I the credit if not the value of calamine is very much raifed, fince an ingenious countryman of ours discovered that it was the true mine of zine; this countryman was Dr. I. Lawson, who died before he had made any advantage of his discovery. The authors of the Supplement to Chambers' Dictionary, published in 1753, expressly affirm, that " ( Dr. Lawfon was the first person who shewed that calamine contained zinc; we have now on foot at home a affor I'be celebrated Brandt, in 1779. sincy; and foon after D. Swat affinity extraffe.

Artic, Calam. & Zinc.

work established by the discoverer of this ore, which will probably make it very unnecessary to bring any zinc into England."-To all this I shall only add one testimony more, from which it may appear that the English knew how to extract zinc from calamine, before Mr. Van Swab taught the Swedes the method of doing it; though this gentleman, unless I have been misinformed, instructed the late Mr. Champion of Briftol, either in the use of black jack for the fame purpose as calamine, or taught him some improvements in the method of obtaining zinc from its ores. The testimony occurs in a differtation of Henckel's on zinc, published in 1727, he is there speaking of the great hopes which fome persons had entertained of the possibility of obtaining zinc from calamine; hopes, he fays; which had been realized in England, Ce qu' un Anglois arrive depuis peu de Bristole dit avoir vu réussir dans son pays .

The manufactory, however, of zinc was not established at Bristol till about the year 1743, when Mr. Champion obtained a patent for the making of it. About 200 tons of zinc are annually made at the place where the manufactory was first set up; and about seven years ago, zinc began to be made at Henham near Bristol, by James Emerson, who had been many years manager of that Branch under Mr. Champion, and his successor in the business.

Near twenty years ago I saw the operation of procuring zinc from calamine performed at Mr. Champion's copper works near Bristol; it was then a great secret, and though it be now better known, yet I am not certain whether there are any works of the kind yet established in any other part of either England or Europe, except that before mentioned at Henbam. In a circular kind of oven, like a glass house furnace, there were placed six pots of about four feet each

in

<sup>\*</sup> This observation was first published in the 4th vol. of the Acta Physico-Medica Acad. Nat. Cur. 1737, but I have made the quotation from the Ed. of Henckel's Works, published at Paris, 1760, Vol. II. p. 494.

in height, much refembling large oil jars in shape; into the bottom of each pot was inferted an iron tube, which paffed through the floor of the furnace into a veffel of water. The pots were filled with a mixture of calamine and charcoal, and the mouth of each was then close stopped with clay, The fire being properly applied, the metallic vapour of the: calamine iffued through the iron tube, there being no other: place through which it could escape, and the air being excluded, it did not take fire, but was condenfed in finall particles in the water, and being re-melted, was formed into ingots, and fent to Birmingham under the name of zinc or spelter \*. The reader will understand that this zinc will be more or less pure, according as the calamine is free from or mixed with iron, lead, copper, or other metallic fubitances. At Goffer, in Germany, they finelt an ore which contains lead, and filver, and copper, and iron, and zinc in the fame mass; the ore is smelted for the purpose of procuring the lead and filver, and by a particular contrivance in the furnace, which is well described by Cramer to they obtain a portion of zinc in substance; another portion of it is inflamed, and the aftes of the zinc which is thus confirmed, and which it has been observed before are called philosophic wool, &c. flick to the top and fides of the furnace, and are denominated by the finelters, radmia fornacum, or furnace fragment : these ashes are used as calamine is for the making of brafs. We know nothing of the method of fluxing the zinc which is brought from India. According to Mulichenbroek, a cubic foot of Indian zinc weighs 7240 ounces; the fame bulk of Gollar zinc, taking the medium of three specimens, gave 7210 ounces 1; the Goslar zinc, which I examined, gave only 6953 ounces to a cubic foot; a cubic

<sup>\*</sup> There is another fubstance which is denominated spelter, or spelter solder by the braziers, it is composed of two parts † Ars Docim. Vol. I. p. 236. ‡ Introd, ad Phil, Nat. Vol. II. of zine and one of brass.

a cubic foot of English zinc, from Bristol, weighs 7028, and hence if the lightness of zinc be a criterion of its purity, our English zinc is preferable to the Indian, and nearly equal to the German zinc.

If the reader has never feen a piece of zine, it will give him some idea of it to be told, that in colour it is not unlike lead; that it is hard, and fonorous, and malleable in a finall degree; that it does not melt fo easily as either tin or lead, but more eafily than filver or copper; that in a degree of heat just sufficient to melt it, it burns away into a kind of gray ashes without being inflamed; that in a stronger heat it burns with a yellowish blue or green same, refolving itself into a white earth, which is either driven off by the violence of the fire during the combustion, or remains furrounding the burning zinc like a piece of cotton wool. This combustion of zinc is as striking an experiment as any in chemistry, and it is in the power of any person to make it, by fprinkling filings of zinc on a pan of burning charcoal, or on a poker or other piece of iron heated to a white heat; it is this property which renders fine filings of zinc of great use in fire works. Zinc is a very fingular metallic fubstance, it not only burns when sufficiently heated with a vivid flame, but it yields an inflammable air by folution in the acids of vitriol and of feat falt, and even in some of its ores it manifests a phosphoric quality; I have feen a piece of black jack from Freiberg, which being feratched in the dark with the nail of a finger emitted a Arong white light. The Chinese zine is faid to contain about half a pound of lead in an hundred, and the German zinc fomewhat more, and our English zinc is thought by fome to make the copper with which it is melted harsher and less malleable, than when either of the other forts of zinc is used; though this opinion I suspect is rather founded in prejudice than in truth. There is an easy method, when pure ginc is required, of obtaining it; nothing more is requisite than

<sup>\*</sup> Berg, Eff, Vol. II. p. 318, note.

than to melt it with fulphur and some fat substance to prevent its calcination, for the fulphur will unite itself to the lead, the copper, or the iron contained in the zine, and reduce them to a kind of fcoria which may be separated from the melted zinc, but it has no action on the zinc itself \*. The zinc made by Mr. Emerson is whiter and brighter than any other either English or foreign zinc, but I do not know that it owes these qualities to its being purified by fulphur, Zine and copper when melted together in different proportions, constitute what are called pinchbecks, &c. of different yellow colours. Marggraf melted pure zinc and pure copper together, in a great variety of proportions, and he found that eleven, or even twelve parts of copper being mixed with one part of zinc, (by putting the zinc into the copper when melted) gave a most beautiful and very malleable tombac or pinehbeck +. Mr. Banné gives the following process for making a metal which he fays is called Or de Manheim, and which is used for imitating gold in a variety of toys, and also on lace. Melt an ounce and an half of copper, add to it three drams of zinc, cover instantly the mixture with chargoal dust to prevent the calcination of the zinc 1; this covering of the melted mass with chargoal is certainly serviceable in the way the author mentions; and it is on a fimilar principle, that when they mek steel at Sheffield, they keep the furface of it covered with charcoal; but I think it probable also, that the charcoal contributes to exalt the golden colour of the pinchbeck. These yellow metals are seldom so malleable as brafs, on account of the zinc which is used in making them not being in fo pure a flate, as that is which is combined with copper when brafs is made; yet it appears from the experiments

<sup>\*</sup> I am aware that Mr. Morveau has found out a method of combining zinc with fulphur; but in this general view, I purposely pass over many things, which are deservedly esteemed of great importance by persons deeply skilled in chemistry.

<sup>†</sup> Mem. of Berlin, 1774. 1 Chy. par M. Baume, Vol. II. p. 662.

experiments of Marggraf and Baumé before mentioned, that when pure zinc and pure copper are used in proper proportions, very malleable brass may be made thereby. Mr. Emerson has a patent for making brass with zinc and copper, as I have been informed, and his brass is said to be more malleable, more beautiful, and of a colour more resembling gold than ordinary brass is. It is quite free from knots or hard places, arising from iron, to which other brass is subject, and this quality, as it respects the magnetic needle, renders it of great importance in making compasses: The method of

making ordinary brafs I will now describe.

Copper in thin plates, or, which is better, copper reduced (by being poured, when melted, into water) into grains of the fize of large fhot is mixed with Calamine and charcoal, both in powder, and exposed in a melting pot for several hours to a fire not quite strong enough to melt the copper, but sufficient for uniting the metallic earth of the calamine to the phlogiston of the coal; this union forms a metallic fubstance, which penetrates the copper contiguous to it, changing its colour from red to yellow, and augmenting its weight in a great proportion. The greater the furface of a definite weight of copper, the more space has the metallic vapour of the calamine to attach itself to, and this is the reason that the copper is granulated, and that it is kept from melting and running into a mass at the bottom of the vessel, till near the end of the operation, when the heat is increased for that purpofe.

The German brass-makers, in the time of Erchern, used to mix 64 pounds of small pieces of copper with 46 pounds of calamine and charcoal, and from this mixture, they generally obtained 90 pounds of brass \*. Cramer recommends 3 parts of powdered calamine to be mixed with an equal weight of charcoal dust and 2 parts of copper, and says, that the brass obtained by the process exceeds the weight

<sup>\*</sup> Fleta Minor. by Sir J. Pettus, p. 286. Newman gives the same proportions, p. 65.

of the copper by a fourth, or even a third part of its weight. At most of our English brass-works they use 45 pounds of copper to 60 pounds of calamine for making ingot brafs. and they feldom obtain less than 60 or more than 70 pounds of brass; at Holywell, they reckon the medium product to be 68: and hence a ton of copper, by this operation, becomes rather more than a ton and an half of brass. This is a larger increase of weight in the copper, than is observed in any of the foreign manufactories that I have ever read of, and it may be attributed to two causes, to the superior excellence of our calamine, and to our using granulated copper. Postlethwayte, in his Commercial Dictionary, attributes the difference in the increase of weight acquired by the brass to the different natures of the coppers which are used. "f there is an increase of 48 or 50 pounds in an hundred, if copper of Hungary or Sweden be used; that of Norway yields but 38, and that of Italy but 20." When they, make brass which is to be cast into plates, from which pans and kettles are to be made, and wire is to be drawn, they use calamine of the finest fort, and in a greater proportion than when common brass is made, generally 56 pounds of calamine to 34 of copper. Old brafs, which has been frequently exposed to the action of fire, when mixed with the copper and calamine in the making of brafs, renders the brafs far more ductile and fitter for the making of fine wire than it would be without it; but the German brafs, particularly that made at Nuremberg, is, when drawn into wire, faid to be preferable to any made in England for mulical instruments. If this preference be real, it will ceafe to exist as soon as any ingenious man shall undertake to examine the subject, for our materials for making brafs are as good as any in the world. The quantity of charcoal which is used, is not the fame at all works, it is generally about a fourth part of the weight of the calamine; an excess of charcoal can be attended with no other inconvenience than that of uset hinter, by Eir J. Pastus, p. 486. Presents gives

lefsly filling up the pots in which the brafs is made ; but powdered pitcoal, which is used at some works in conjunction with, or in the place of charcoal, greatly injures the malleability of the brafs. As to black jack, the other ore of zinc, it is not fo commonly used as calamine for the making of brafs. The manufacturers have been fomewhat capricious in their fentiments concerning it, fome have preferred it to calamine, and others have wholly neglected it; and the fame persons at different times have made great use of it, or intirely laid it afide. There must have been some uncertainty in the produce or goodness of brass made by this mineral, to have occasioned such different opinions concerning it, and this uncertainty may have proceeded either from the variable qualities of the mineral itself, or from the unskilfulness of the operators in calcining, &c. a mineral to which they had not been much accustomed. Several ship loads of it were fent a few years ago from Cornwall to Briftol, at the price of 40 shillings down to a moidore a ton ". Upon the whole, however, experience has not brought it into reputation at Briffol, battern view and the soul

For many purpoles brafs is more uleful than copper: it is lighter; harder, more fonorous, more fufible, lefs liable to scale in the fire, and to ruff in the air. It is not malleable when hot, and in this respect it is inferior to copper; but when cold it may he beat out into thin leaves, as may be feen in the brafs leaf which emulates in colour and thinness gold leaf. If a brafs leaf be held in the flame of a candle, the metallic part of the calamine will be inflamed, and the brafs will be changed into copper. This change of brafs into copper will take place in the largest masses, as well as in thin leaves of it, if the brafe be kept a fufficient time in a state of fusion. The varieties in the colour; malleability, and ductility of brafs, proceed from the quantity and quality of the calamine imbibed by the copper; and the quality of the copper itself is sonefamozio a de Chert. Let a wir, notes, p. 6g.

a circumstance of no small importance in the making of brafs. " I have observed, fays Dr. Lewis", in a large set of experiments on this fubject, that a little of the calamine (that is, of the zinc contained in the calamine) dilutes the colour of the copper and renders it pale; that when the copper has imbibed about one twelfth of its own weight, the colour inclines to yellow; that the yellowness increases more and more till the proportion comes almost to one half; that on further augmenting the calamine, the brafs becomes paler and paler, and at last white." As to the different qualities of different kinds of copper, they are fufficiently known to workmen employed in fabricating it; and philosophers have so far observed them as to diffinguish the different forts of copper by the different weights which appertain to equal bulks of them. The lightest copper which Muffchenbroek has noticed, is, that which is pro pitated from the copper waters in Hungary; a cubic foot of this fort weighed, when melted, 7242 ounces; and the heaviest fort he mentions is the Jopan copper, a cubic foot of it, when simply melted, weighing 8926 ounces. The difference of the weights of equal bulks of these two forts of copper is very confiderable; but yet it is much lefs than what may be observed between two spermens of the fame fort of copper, one of which has been caft, and the other has been wrought: the fame Hungarian copper, which, when barely melted, weighed 7242 ounces to she cubic foot, when is had been condensed by being long hammered, weighed 9020. Many of our English writers estimate the weight of a cubic foot of copper at 9000 ouncest, but they do not fay, whether the copper was melted merely, or hammered, nor from what mine it was procured. I found the weight of a cubic foot of plate-brafs from Bristol to be 8441 ounces; and that of a cubic foot of Moreton from the quaetity and quality of the criticists in-

bibed by the coppensional the quality of the copper inch se-

Newman's Chem. by Lewis, notes, p. 65.

<sup>†</sup> Cotes, Ferguson, Martin, Campbell.

old brass from the bottom of an old kettle to be 8819, which shews that it approached to the weight of copper, and indeed from the redness of its appearance it feemed as if all the zinc had been burned away. I had a prefent made me of a fine celt, (the antiquaries are not agreed concerning the uses to which the celts were applied, nor whether they are to be esteemed British or Roman instruments) it was covered over with a thick patina; I heated it in the fire, in order to get rid of this precious patina, or green ruft, and took the specific gravity of it when quite freed from its ruft with great care; a cubic foot of it would have weighed only 6290 ounces. It was not malleable either when hot or cold: I then melted it, when in a state of fusion it emitted a blue stame, and a thick white smoke, which are esteemed certain marks of zinc; I melted it a fecond time, but there was no appearance of either flame or fmoke, the zinc having been all confumed; I could not observe any lead in it; a cubic foot of it, after it was gently cooled from its state of fusion, weighed 8400 ounces, and it was now malleable as cold brafs always is; it was composed, I think, of copper, calamine and tine and I have heard that fome celts contain a little filver. The change of texture which it had undergone, by being long buried in the earth, occasioned its comparative levity; this diminution of weight, which decaying brafs fultains, is not peculiar to brafs, it probably belongs to iron, and other metallic fubstances subject to decay; and it certainly belongs to many species of stones. I have in another place observed, that a cubic foot of toadstone has different weights, according as the stone is more or less decayed; that which is most decayed being the lightest. We have a stratum of bluish gray ragsone in Westmoreland, which lies under the limeftone; large cobbles of this fort of stone, which are exposed to the air, are decayed to a certain depth from the furface, whilst the inward part seems intire; a cubic foot of the outward part of one of these Gg VOL. II.

stones weighed 2378, when the inward part of the same stone weighed 2003 ounces to the cubic foot. This ragstone is very hard, but the same phenomenon may be noticed in a stone still harder. The Cambridgesbire black flint weighs 2592 ounces to the cubic foot; the fame flint being in part decayed and become externally white, though black within, weighed 2414, and when become wholly white, 2400 ounces to the cubic foot: the general reason of this feems to be, that the pores of the decayed body are augmented. Mr. Kirwan has well explained the manner in which nature operates in decomposing stones. \* Flints, jaspers, petro-filex, feltspar, granites, lavas and ferrogineous stones, have frequently been faid to be decomposed by the air, and the observations of Mr. Greville and Sir W. Hamilton have removed every doubt I entertained on this head. With regard to furrugineous stones, in, which the calx of iron is not much dephlogisticated, this decompolition is easily understood, for this calx gradually becomes more dephlogisticated by the action of water and air, attracts water and fixed air, and lofes its adherence with the filiceous, or other stony particles: this is feen to happen to bafaltes, toadstone, ferrugineous limestone, &c. In other flowes this decomposition may arise from their containing calcareous earth in a caustic state, or manganese, for these will gradually attract water and fixed air, and then fwell, burst and loofen the whole texture of the stone, as we fee happen to bricks that contain lime. Thus also glass is decomposed by long exposure to the air, the alkali attracting water and aerial acid. Mortar on the contrary hardens by long exposure to the air, because, though the aerial acid be attracted, yet a great part of the water exhales"." The changes produced by the long exposure of bodies to the air, and the causes of them, deserve a more minute investigation than has hitherto been bestowed on

Delitario del la segui

<sup>\*</sup> Elements of Min. by R. Kirwan, p. 111.

them; fome advantage might, perhaps, be derived from the inquiry to our manufacturers, for I have cause to think that iron, which has been exposed to the air for three or four years, is a very different substance from the same iron when just made: and the same observation will probably hold with respect to copper and brass. — But to return from this digression.

The calamine of Bohemia contains iron; most of our English calamine contains lead; and there are some forts which contain both iron and lead, and other metals in different proportions: these forts can seldom be freed from the extraneous metals, and hence, in the ordinary method of making brafs, they will be mixed with it, being fusible in the degree of heat usually employed in making brafs. Cramer mentions a very ingenious method of making brafs, by which, if it should be thought necessary to do it, the brass may be preserved pure from these heterogeneous mixtures. He orders the calamine and charcoal to be mixed with moistened clay, and rammed to the bottom of the melting pot, and the copper mixed with charcoal to be placed upon the clay; then, the proper degree of heat being applied, the vapour of the zinc contained in the calamine will ascend through the clay, and attach itself to the copper, but the iron, or lead contained in the calamine, not being volatile, will remain in the clay, and the brass when the whole is melted will not be mixed with them, but rest pure on the surface of the clay. Mr. John Champion, brother to him who first established the manufactory of zinc at Bristol, is a very ingenious metallurgift, and he has lately obtained a patent for making brafs by combining zinc in vapour with heated copper plates, and the brass is said to be very fine; whether the process he uses has any correspondence with this mentioned by Cramer, or not, his brass will certainly be free from the mixture of lead, &c. But the care to purify brafs from such metallic mixtures as may be accidently contained in the calamine, is, or is not necessary, according to the purposes to which brass Gg2 is

is applied. These mixtures may probably injure the malleability of the brass but they may at the same time increase its hardness, or render it susceptible of a better polish, or give it a particularity of colour, or fome other quality by which it may be more useful in certain manufactories, than if it was quite free from them, and confifted of nothing but of the purest metallic part of the calamine, united to the purest copper. This may be illustrated from what is obsevable in other metals. The red iron ore from Furness in Lancashire produces an iron, which is as tough as Spanish iron, it makes very fine wire; but when converted into bars, it is not esteemed fo good as that which is made in the forest of Dean, and other places. There are but few forts of iron which, though useful in other respects, are fit for being converted into steel: some forts of iron will admit an high polish, as may be feen in many expensive grates which are fold as grates of polished steel, though they are nothing but iron, whilst others take but a very indifferent polish; the Swedish, Russian, and English irons, and even the irons made at different furnaces in the fame country, are respectively fit for some purposes, and unfit for other; he who should attempt to use the same iron for the making of wire, and for coach and waggon wheels, would betray great ignorance in his business. In like manner, a notable difference may be obferved in different forts of copper, yet all of them have their respective uses: the Swedish copper is more malleable than the copper of Hungary; the copper of Anglesey differs from the copper of Cornwall and of Staffordshire. The braziers prefer that copper which they can work with the greatest facility, but the malleability of copper should not be esteemed the only criterion of its goodness; for the copper which is less malleable may admit a finer polish, and may last longer when exposed, as in breweries, in the navy, &c. to the action of the fire, than the copper which is more malleable. This has been proved by experiment. Three plates of copper, equal to each other in furface and thicknefs.

ness, were exposed for the same length of time, to a violent sire, with a view of seeing which would best sustain its action; one plate was made of copper which had been purished by a chemical process, another was made of copper from Hungary, and the third of Swedish copper. The purished copper, when freed from the calcined scales, had lost 5 grains of its weight, that of Hungary had lost 8, and that of Sweden 11 grains.

Queen Elizabeth, in 1565, granted by patent all the calamine in England and within the English Pale in Ireland to her affay mafter William Humphrey, and one Christopher Shutz a German, and, as the patent fets forth, a workman of great cuaning, knowledge and experience, as well in the finding of calamine, as in the proper use of it for the composition of the mixt metal called latten or brass +. With these patentees were soon after associated some of the greatest men in the kingdom, as Sir Nicholas Bacon, the Duke of Norfolk, the Earls of Pembroke and Leicester, Lord Cobham, Sir William Cecil, and others, and the whole were incorporated into a fociety, called, The Society for the Mineral and Battery Works in the year 1 568. Mines of latten, whatever may have been at that period meant by the word, are mentioned in the time of Henry VI. who made his chaplain John Bottwright, comptroller of all his mines of gold and filver, copper, latten, lead, within the counties of Devon and Cornwall t; yet I am disposed to think, that the beginaing of the brass manufactory in England may be properly referred to the policy of Elizabeth, who invited into the kingdom various persons from Germany, who were well skilled in metallurgy and mining. In 1639, a proclamati-Gg2

on was iffued prohibiting the importation of brafs wire "; and about the year 1650, one Demetrius, a German, fet up a brass work in Surrey, at the expence of fix thousand pounds +, and above eight thousand men are said to have been employed in the brass manufactories, which were eftablished in Nottinghamshire, and near London, yet Sir John Pettus, in his account of royal mines, published in 1670, observes that these brass works were then decayed, and the art of making brass almost gone with the artists ‡. But though the art was then almost gone, yet it was never, after its first establishment, altogether lost; for about the year 1708, we find that there were brafs manufacturers in England, and that they presented a memorial to the House of Commons, fetting forth feveral reasons for continuing the brass manufactory in this kingdom, and soliciting for it the protection of parliament 6. In this memorial they stated that England, by reason of the inexhaustable plenty of calamine, might become the staple of brass manufactory for itfelf and foreign parts; that the continuing the brafs works in England would occasion plenty of rough copper to be brought in, and make it the staple (in time) of copper and brafs; that the Swedes had endeavoured to subvert the English brass manufactory, by lowering the price of Swedish brass wire, inveigling away workmen, and other means. In compliance with the purport of this memorial, an act of parliament was passed in the same year, by which the former duties payable on the exportation of copper of the produce of Great Britain, and of brafs wire, were taken off, and thefe articles were allowed to be exported free of duty. In 1720 it was remarked that this nation could fupply itself with copper and brafs of its own produce fufficient for all occasions, if fuch duties were laid on foreign copper and brafs, as would discourage their importation, and at the same time en-

courage the fale of our own metals \*. At present the brass manufactory is established amongst us in a very great extent; we are fo far from being obliged to have recourse to any of our neighbours for this commodity, that we annually export large quantities of manufactured brafs to Flanders (it' was formerly called Flanders metal) France, Germany, Portugal, Spain, Russia, Africa, and most other parts of the world. In 1783, a bill was passed by the House of commons for repealing certain statutes prohibiting the exportation of brafs. In the reign of Edward III, the exportation of iron, either made at home or brought into England, had been prohibited upon the pain of forfeiting double the value of the quantity exported +. And in the reigns of Henry VIII. and Edward VI. several acts of parliament had been passed, prohibiting the exportation of brafs, copper, latten, bell-metal, pan-metal, gun-metal, shrof-metal, under the same penalty t. The general reason for passing these acts certainly does not apply to the present state of our mines and manufactures, for the reason was this, -left there should not be metal enough left in the kingdom fit for making of guns and other engines of war, nor for houshold utenfils. The forementioned acts of Parliament were partially repealed, by an act passed in the sixth year of William and Mary, by which it was rendered lawful to export, after the 25th of March, 1694, all manner of fron, copper, or mundick metal; but the prohibition of the other metals was continued. The brafs-makers in 1783 applied for the same liberty, which had been granted to the iron and copper smelters, a liberty of exporting the crude commodity; this liberty was not granted them by the legislature, for the

bill which had passed the House of Commons, was thrown out by the Lords, The Birmingham manufacturers prefented a petition to the house of commons against the bill which was then pending; in which petition it was reprefented—that frequent attempts had been made to erect manufactures similar to those of Birmingham in different parts of Europe, and that the excellence of some of the Birmingham articles depended upon brafs of very different qualities, and that, fortunately for this country, there were feveral forts of brafs that were peculiarly adapted to the different branches of their manufactures; fo that the fort which was finitable for one article, was improper for another: and that they had reason to believe, that the manner of adapting the various forts of English brass to different articles in their manufactures, was not known to foreigners; but that if free liberty was given to export brafs, every maker might be induced to discover the peculiar uses of his fort, and that very difagreeable confequences to their manufactures might there-The petitioners also represented—that by be produced. brass-makers, in different provinces of this kingdom, had not fucceeded in making the forts of brass made in other provinces; and that one great company of brafs-makers had not fucceeded in making brafs fuitable for the Birmingham market, though they had professed an earnest desire to do so. And they humbly apprehended, that there never had been fuch a quantity of brass exported as to render it a national object, and that there was not a probability of any fuch quantity being exported, though so much might be as to raise a ruinous competition to their manufactures, &c.

The brass-makers, it may be said, suffer an injury in being prohibited from exporting a commodity by which they might be gainers, merely lest the great brass manufacturers should lose somewhat of their profit, by having a less extensive trade. But this is not a proper state of the case; it is not for the sake of the great brass manufacturers, that the prohibition of exporting brass is continued, nor is there any

want of that metal in the kingdom; but lest foreigners should rival us in a trade which, in affording employment to many thousands of people, is of the greatest consequence to the kingdom in general. The proprietors of Fuller's Earth have been prohibited from exporting that material, not out of any partial regard of the legislature for the great woollen manufacturers, but lest the number of persons employed in that manufacture should be much lessened, if foreigners were fupplied with an article fo effentially necessary to its perfection, as fuller's earth is found to be; and though other nations have fuller's earth, yet that which is met with in England is reckoned to be fitter for the woollen manufactory, than any other which has yet been found in any part of the world. This observation may be applied to the fubject we are speaking of. Great quantities of good brass are made by most nations in Europe, as well as by the English; but the English brass is more adapted to the Birmingham manufactories, than any other fort is; and hence in France, Portugal, Ruffia, and Germany, our unmanufactured brass is allowed to be imported free of duty, but heavy duties are imposed in those countries on manufactured brafs when imported. The manner of mixing different forts of brafs, fo as to make the mixture fit for particular manufactures, is not known to foreigners, though this is a circumstance of the greatest importance; but there can be little doubt that if foreign nations were possessed of all the forts of English brass, they would foon feduce our workmen to instruct them in the manner of mixing them, and in fome other little circumstances which are not generally known, but on which the fuccess of the manufacture depends in a great degree. On these and other accounts, till commerce puts on a more liberal appearance than it has hitherto done in Europe, till different nations shall be disposed to consider themselves, with respect to commercial interests, as different provinces only of the fame kingdom, it may, probably, be thought expedient

expedient to continue the acts prohibiting the exportation of unwrought brass, though the reasons which induced the legislature to pass them, have long since ceased to exist. I do not enter into the inquiry, when the cultom house officers began to make a distinction between wrought and unwrought brass, so as to admit the former to an entry for exportation, and not the latter; but I apprehend it was in the year 1721, when various goods and merchandizes of the product or manufactures of Great Britain were allowed, by act of parliament, to be exported free of duty : lapis calaminaris, lead, and feveral other articles are enumerated in the act, on which the duty was to be continued; but in this enumeration, there is no mention made of unwrought brafs, though it may properly be confidered as a merchandize of the product of Great Britain; but the quantity of brafs which was then made in the kingdom was fo fmall, that it did not, probably, enter into the contemplation of the legislature to forbid an exportation, which did not feem likely ever to take place. Brass is made in various parts of Great Britain; but the Briftol, Macclesfield, and Warrington companies are the only ones, I believe, which go through all the proceffes of finelting the copper from its ore, of preparing the calamine, and of uniting it with copper for the making of brass. The trade of brass-making has within these few months been much deranged throughout the nation, by an agreement which has been entered into by some of the principal copper companies, to the exclusion of others, to buy up all the copper of the mines now at work in the kingdom. The effect of this plan is not yet generally either felt or forefeen.

The following effay was written feveral years ago; it is now printed, with little alteration, from a copy which I transmitted in 1783, to The Literary and Philosophical Society at Manchester, as a small Tribute of Gratitude for the unfolicited and unexpected honour they had done me, in electing me one of their members.

### ESSAYXXX

in colour, is obtained at min inches both birth a colour of tracks

On Orichalcum.

WE have a proof, from the writings of Cicero, that the Romans, in his time, understood by the term Orichalcum, a metallic substance resembling gold in colour, but very inferior to it in value. He puts the following case.—"Whether, if a person should offer a piece of gold to sale, thinking that he was only disposing of a piece of Orichalcum, an honest man ought to inform him that it was really gold, or might fairly buy for a penny what was worth a thousand times as much." It is not contended, that the argument, in this place, required any great accuracy in ascertaining the relative values of gold and orichalcum; yet we may reasonably conclude from it, that orichalcum might by an ignorant person be mistaken for gold, and, that it was but of small estimation when compared with it.

Julius Cafar robbed the capitol of three thousand pound weight of gold, and substituted as much gilded copper in its stead +; in this species of facrilege, he was sollowed by Vitellius, who despoiled the temples of their gifts and ornaments, replacing the gold and silver by tin and orichalcum ‡. From this circumstance also, we may collect, that the Roman orichalcum resembled gold in co-

lour, though it was far inferior to it in value.

It is probable, that the orichalcum here spoken of, was a metallic substance greatly analogous to our brass, if not wholly the same with it. The value of our brass is much less than that of gold, and the resemblance of brass to gold

<sup>\*</sup> Cicer. de Off. L. III. † Suet. in Jul. Cæf. C. LIV. ‡ Id. in Vitel. C. VI.

in colour, is obvious at first sight. Both brass and gold, indeed, are susceptible of a variety of shades of yellow; and, if very pale brass be compared with gold mixed with much copper, such as the foreign goldsmiths, especially, use in their toys, a disparity may be seen; but the nearness of the resemblance is sufficiently ascertained in general, from observing that substances gilded with brass, or, as it is commonly called, Dutch leaf, are not easily distinguished from

fuch as are gilded with gold leaf.

The Romans were not only in possession of a metallic substance, called by them orichalcum, and refembling gold in colour, but they knew also the manner of making it; and the materials from which they made it, were the very fame from which we make brass. I am fensible, that in advancing this opinion, I diffent from authors of great credit, who esteem the art of making brass to be wholly a modern invention. Thus M. Cronftedt (though I differ in opinion from him) " does not think it just to conclude from old coins and other antiquities, that it is evidently proved, that the making of brafs was known in the most ancient times";" the authors of the French Encyclopedie affure us, "that our brass is a very recent invention +;" and Dr. Laughton t fays, " the veffels here called brazen, after ancient authors, cannot have been of the materials our present brass is composed of, the art of making it is a modern discovery."

Pliny, speaking of some copper which had been discovered near Corduba in the province of Andalusia in Spain, says, "this of all the kinds of copper, the Livian excepted, absorbes most cadmia, and imitates the goodness of aurichalcum s." The expression, 'absorbs most cadmia,' seems to indicate, that the copper was increased in bulk, or in weight, or in both, by means of the cadmia. Now it is well known, that any definite quantity of copper is greatly increased

<sup>\*</sup> Miner. p. 218. †Art. Orichalque. †Laughton's Hist. of Ancient Egypt. p. 58. § Hist. Nat. L. XXXIV. S. II,

increased, both in bulk and in weight, when it is made into brass by being sluxed in conjuction with calamine. The other attribute of the copper when mixed with cadmia, was, its resembling aurichalcum. We have seen from Cicero, that the term orichalcum was applied to a substance far less valuable than gold, but similar to it in colour; and it is likely enough, that the Romans commonly called the mixture of copper and cadmia orichalcum, though Pliny says, that it only resembled it; he, as a naturalist, speaking with precision, and distinguishing the real orichalcum, which in his time, he says, was no where produced, from the factitious one, which, from its resemblance to it, had usurped its name.

Sentus Pompeius Festus abridged a work of Verrius Flaccus, a grammarian of considerable note in the time of Augustus. In this abridgement, he defines cadmia, to be an earth which is thrown upon copper, in order to change it into orichalcum. The age in which Festus stourished is not ascertained: he was unquestionably posterior to Martial, and some have thought that he lived under the Christian Emperors. But leaving that point to be settled by the critics, if he expressed himself in the words of the author, whose work he abridged, we have from him a decisive proof, the cadmia was considered as a species of earth, and that the Romans used it for the converting of copper into a metallic substance called, in the Augustan age, orichalcum.

In opposition to this, it ought to be remarked, that some understand by the cadmia of Pliny, not calamine, but native arsenic. They seem to have been led into this opinion, from observing that Pliny says, lapis erosus was called cadmia. For, apprehending that by lapis erosus, Pliny understood a kind of stone which caused ulcars and erosions in the siesh of those who were occupied in working it, and knowing

<sup>\*</sup> Cadmia-Terra que in es conjicitur, ut fiat orienalcum. Fes. de Ver. Seq.

knowing that arfenic produced such an effect, they have concluded that cadmia was native arsenic. This probably, is a mistake, arising from a misinterpretation of the word, arosus. Pliny usually, if not constantly, applies that word to substances in which copper is contained, without having any respect to the actions of such substances on the slesh of animals. Arsenic, moreover, when mixed with copper, does not give a gold, but a silver-like appearance to copper. And lastly, Pliny + in another place expressly says, that the stone from which brass (as) was made was called cadmia; now it is impossible to make either brass or copper from arsenic.

Ambrose, bishop of Milan in the fourth century, says, that copper, mixed with certain drugs, was kept sluxed in the furnace till it acquired the colour of gold, and that it was then called aurichalcum t. Primasius, bishop of Adrumetum in Africa, in the sixth century, observes, that aurichalcum was made from copper, brought to a golden colour by a long continued heat, and the admixture of a drug s. Isidorus, bishop of Seville in Spain, in the seventh century, describes aurichalcum as possessing the spleadour of gold, and the hardness of copper, and he uses the very words of Primasius respecting the manner of its being

<sup>\*---</sup> nous soupconnons que Pline a voulu designer par lapis ærosus, une pierre qui mange et fait des ulceres ou érosions a ceux qui la travaillent, et qui est probablement l'arsenic vierge. Miner. par M. Valmont de Bomare, V. II. p. 64.—If the word had been erosus, this criticism might have been admitted.

<sup>+</sup> Hift. Nat. L. XXXIV. 10.

Les namque in fornace, quibusdam medicaminibus admixtis, tamdiu constatur, usque dum colorem auri accipiat, et dicitur auri-chalcum. Amb. in Apoc. C. I.

<sup>§</sup> Aurichalcum ex ære fit, cum igne multo; et medicamine adhibito, perducitur ad aureum colorem. Prima. in Apoc. C. I.

ing made ¶. The drug spoken of by these three bishops was probably cadmia. Prepared cadmia is highly commended by Pliny as useful in disorders of the eyes ||, and it is still with us, under the more common appellation of calamine, in some repute for the same purpose. Hence, considering the testimonies of Festus and Pliny to the application of cadmia in making either orichalcum, or a substance imitating the goodness of orichalcum, we cannot have much doubt in supposing that cadmia was the drug alluded to by Ambrase, and by those who seem to have borrowed, with some inaccuracy of expression, his description of the manner of making orichalcum.

What we call brass, was anciently in the French language called archal, and brass wire is still not unfrequently denominated fil d' archal. Now if we can infer from the analogy of languages, that archal is a corruption of aurichalcum, we may reasonably conjecture, that our brass, which is the same with the French archal, is the same also with the Roman aurichalcum.

Though we may, from what has been advanced, conclude, without much apprehension of error, that the Romans knew the method of making brass, by melting together calamine and copper; yet the invention was probably derived to them from some other country.

We meet with two passages, one in Aristotle, the other in Strabo, from which we may collect, that brass was made in Asia, much after the same manner, in which it appears to have been made at Rome.

Strabo informs us, that in the environs of Anders, a city of Phrygia, a wonderful kind of stone was met with, which being calcined became iron, and being then fluxed with a certain earth, dropped out a silver-looking metal, which,

¶ Aurichalcum dictum, quod et splendorem auri, et duritiam æris possideat, sit autem ex ære et igne multo, ac medicaminibus perducitur ad aureum colorem. Isid Orig.

Hift. Nat. L. XXXIV. C. X.

which, being mixed with copper, formed a composition, which some called orichalcum. It is not improbable, I think, that this stone resembled black jack, or some other ore of zinc. Black jack, may, in a common way of speaking, be called a stone. It abounds in iron; and, when calcined, looks like an iron earth: it yields zinc by distillation, sometimes mixed with silver and lead; and both the metallic substance which may be extracted from black jack, and the substance which arises from it, whilst it is smelted, will, when mixed with copper, make brass.

The Mossynaci inhabited a country not far from the Euxine Sea, and their copper, according to Avistotle, was faid to have become solendid and white, not from the addition of tin, but from its being mixed and cemented with an earth found in that country +. This cementing of copper with an earth, is what is done, when brafs is made, by uniting copper with calamine, which is often called, and, indeed, has the external appearance of, an earth: and that Afia was celebrated for its cadmia or calamine, we have the testimony of Pliny 1. The copper of the Mossynaci is said to have become white by this operation. Whiteness appertains to brafs, either absolutely, or relatively: for brafs is not only much whiter than copper; but when it is made with a certain quantity of a particular fort of calamine, for there are very various forts of it, its ordinary yellow colour is changed into a white. Cicero, we have feen, fupposes that orichalcum might have been mistaken for gold, and as fuch, it must have been yellow; yet Virgil applies the epithet white to orichalcum.

<sup>§</sup> Virg. Æt. L. XII. 87.

Ariffotle also speaks of having heard of an Indian copper, which was thining, and pure, and free from ruft, and not diftinguishable in colour from gold ; and he informs us, that amongst the vessels of Darius there were some, of which, but for the peculiarity of their [mell, it would have been impossible to fay, whether they were made of gold or copper. This account feems very descriptive of common brais, which may be made to refemble gold perfectly in colour, but which, upon being handled, always emits a firming and peculiar finell, not observable either in gold or gilded copper in this man and the first or loved and read

The kings of Perfia, who preceded the Darius mentioned by Arifotte, were in possession of similar vessels; but they feem to have been rare, and of course were held in high estimation. Among the magnificent prefents of gold and filver veffels, which Artaxerxes and his counfellors gave to Ezra, for the fervice of the temple at Jerufalem, there were twenty basons of gold, and but two vessels of yellow thining copper, precious as gold, or, as fome ren-der the words, relembling gold to "Sir John Chardin, in his MS note, his mentioned a mixt metal used in the east, and highly effected there; and, as the origin of this composition is unknown, it might, for aught we know, be as old as the time of Ezra, and be brought from those are remote countries into Perfla, where these two basons were given to be conveyed to Jerufalem, "I have heard," says the note; fome Dutch gentlemen speak of a metal in the island of Sumatra, and among the Macassars, much more effectued than gold, which royal perfonages alone might weard It is a mixture, if I remember right, of gold or of copper and freel.' He afterwards added to this note (for the colour of the ink differs) "Calmbac is this metal composed of gold and copper. It in colour nearly refembles the pale carnation rose, has a very fine grain, the polish extremely lively. I have seen something Vol. IL at Il loy of Hho Committee

Gen. L. XH

<sup>\*</sup> Arif. de Mirab. T. II. p. 719.

#### 454 CHEMICAL ESSAYS.

of it, &c. Gold is not of so lively and brilliant a colour; I believe, there is steel mixed with the gold and copper.' He seems to be in doubt about the composition; but very positive as to its beauty and high estimation \*."

The supposition of brass having been anciently made in India, feems to be rendered improbable by both Pliny and Strabo; Pliny expressly faying, that the Indians had no copper t, and without copper we are certain that brafs cannot be made; and Strabo reprefenting them as fo ignorant of the art of fluxing metals t, that, according to him, if they had been possessed of the materials, they would not have had the ability to use them for the composing of brass. But these writers, it is apprehended, knew very little of India. Strabo, in particular, laments his want of materials to compose a consistent account of India; and few of the authors, from whose works Pliny compiled his natural history, can be supposed to have had any intercourse with that country. Strabo, moreover, contradicts both Pliny's observation, and his own. In describing the great pomp with which fome of the Indians were accustomed to cele their festivals, he speaks of huge gilt kettles, cups, and tables made of Indian copper \$; from which it appears, not only that the Indians were not destinute of copper, but that they were skilful metallurgists, fince they knew how to flux it, to form it into veffels of various kinds, and to gild it. Perhaps, this Indian copper, of which the veffels were made, inflead of being gilt, only refembled gold in colour, and was really a fort of brafs. It is granted that this is but a conjecture, but it is not devoid of probability a for, not to mention that the author, whoever he was, from whom Strabo extracted this account, might, in a public exhibi have easily mistaken polished beats for gilt copper, nor the little probability, that cauldrons, and kettles, and fuch alelley refembles the pale curation rules has a rule, the

veffels as were in confrant use, would be gilded in any country, we have reason to believe, from what has been obferved before, that a peculiar kind of vessels, probably refembling some of those exhibited in the Indian festivals, had been long in use in Persia, and that they were made of Indian copper without any gilding. We know that there is found in India, not only copper strictly so called, but zinc also, which being mixed with copper, constitutes brass, pinchbeck, tombac, fimilor, and all the other metallic mixtures which refemble gold in colour. On the whole, it appears probable to me, that brafs was made in the most remote ages in India, and in other parts of Afia, of copper and colomine, as it is at prefent. If the celt be allowed to be a British instrument, then may we be certain, from what was obferved concerning it in the fast Essay, that our ancestors knew the method of mixing together calamine and copper; for though in and copper when melted together, in certain proportions, will give a bluish green flame, yet that flame is not accompanied with a thick white Imouk, and there are but few proportions in which any flame at all is to be feet holode to once that we have and have men

With respect to orichalcum, it is generally supposed that there were two forts of it, one factitious, the other natural; the factitious, whether we confider its qualities or composition, appears to have been the same with our brass. As to the natural orienalcum, there is no impossibility in fuppofing; that copper ore may be fo intimately blended with an ore of zinc, or of some other metallic substance, pound, when finelted, may yield a mixed that the com metal of a paler hue than copper, and refembling the co-lour of either gold or filver. In Du Halde's history of China, we meet with the following account of the Chinese abbite copper. . The most extraordinary copper is called Pe-tong, or white copper: it is white when dug out of the mine, and still more white within than without. It appears, by a vast number of experiments made at Peking, Hh2

that its colour is owing to no mixture; on the contrary all mixtures diminish its beauty; for, when it is rightly managed, it looks exactly like filver, and were there not a necessiy of mixing a little tutenag, or some such metal with it, to foften it, and prevent its brittleness, it would be so much the more extraordinary, as this fort of copper is, perhaps, to be met with no where but in China, and that only in the province of Tunnan\*." Notwithstanding what is here faid, of the colour of this copper being owing to no mixture, it is certain, that the Chinese white copper, as brought to us, is a mixt metal; fo that the ore, from which it is extracted, must consist of various metallic fubstances, and from some such ore it is possible that the natural orichalcum, if ever it existed, may have been made. But though the existence of natural orichalcum cannot be shewn to be impossible, yet there is fome reason to doubt, whether it ever had a real existence or not: for I pay not much attention to what father Kircher has faid of orichalcum being found between Mexico and the straits of Darien, because no other author has confirmed his account, at least none on whose skill in mineralogy we may rely +.

We know of no country in which it is found at present; nor was it any where found in the age of Pliny; nor does he seem to have known the country where it ever had been found. He admits, indeed, its having been formerly dug out of the earth; but it is remarkable, that in the very passage, where he is mentioning by name the countries most celebrated for the production of different kinds of copper, he only says, in general, concerning orichalcum, that it had been found in other countries, without specifying any particular country. Plate acknowledges, that orichalcum was a thing only talked of even in his time; it was no where then to be met with, though in the island of Atlan-

middle stirle som hin has stirl

were in possession of a metallic substance, called orichalcum, before the foundation of Rome; for it is mentioned by Homer and by Hesiod, and by both of them in such a manner as shews, that it was then held in great esteem. Other ancient writers have expressed themselves in similar terms of commendation; and it is principally from the circumstance of the high reputed value of orichalcum, that authors are induced to suppose the ancient orichalcum to have been a natural substance, and very different from the factitious one in use at Rome, and, probably, in Asia, and which, it has been shewn, was nothing different from our brass,

But this circumstance, when properly considered, does not appear to be of weight sufficient to establish the point. Whenever the method of making brass was first found out, it is certain that it must have been for some time, perhaps for fome ages, a very scarce commodity; and this scarcity, added to its real excellence as a metallic substance, must have rendered it very valuable, and intitled it to the greatest encomiums. Diodorus Siculus speaks of a people, who willingly bartered their gold for an equal weight of iron or copper ; and the Europeans have long carried on a fimilar kind of commerce with various nations. Gold, in fome views, is justly esteemed the most valuable of metals; in other, and those the most important to the well-being of human kind, it is far inferior to iron, or copper, or brafs. An individual, whose life depended upon the issue of a fingle combat, to be decided by the fword, would have no hesitation in preferring a sword of steel to one of gold; and an army, which should be possessed of golden armour, would not scruple to exchange it, in the day of battle, for the iron accourrements of their enemies. The preference of the harder metals to gold, is not less obvious in agriculture, than in war; a plough-share, spade, mattock, Hh 3 chizel,

chizel, hammer, faw, nail, of gold, is not for ale for valuable, as an infrument of the fame kind made of iron or brafs. Hence, there is no manner of abfurdity in suppoling that orichalcum, when first introduced among the ancients, might have been prized at the greatest rate, though it had been possessed of no other properties, than fuch as appertain to brafs. When iron was either not at all known, or not common in the world, and copper instruments, civil and military, were almost the only ones in use \*, a metallic mixture, resembling gold in splendour, and preferable to copper, on account of its superior hardness, and being less liable to rust, must have greatly excited the attention of mankind, been eagerly fought after, and highly extelled by them. The Romans, no doubt, when it had been stipulated in the league which Porfenna made with them, after the expulsion of the Tarquing, that they fhould not use iron, except in agriculture, must have effeemed a metallic mixture fuch as brafs, at a rate not eafily to be credited +. It is not here attempted to prove, that there never was a metallic fubitiance called orichalcum, fuperior in value and different in quality from brais; but merely to thew, that the common reason assigned for its existence, is not so cogent as is generally supposed.

Confidering the few ancient writers we have remaining, whose particular business it was to speak with precision concerning subjects of art, or of natural history, we ought not to be surprized at the uncertainty in which they have left us

#### to not or had Hellody a mile long at coincid.

with respect to orichalcum. Men have been ever much the fame in all ages; or, if any general superiority in understanding is to be allowed, it may seem to be more properly afcribed to those who live in the manhood or old age of the world, than to those who existed in its infancy or childhood: especially as the means of acquiring and communicating knowledge are, with us, far more attainable than they were in the times of either Greece or Rome. The compais enables us to extend our refearches to every quarter of the globe with the greatest ease\*; and an historical narration of what is feen in distant countries, is now infinitely more diffused than it could have been, before the invention of printing; yet, even with thefe advantages, we are, in a great measure, strangers to the natural history of the earth, and the civil history of the nations which inhabit it. He who imports tutenag from the East Indies, or white copper from China or Japan, is fure of meeting with a ready market for his merchandize in Europe, without being afked any questions concerning the manner how, or the place where they are prepared in. An ingenious manufacturer of these metallic substances might wish, probably, to acquire some information about them, in order to attempt a domestic imitation of them; but the merchant who imports them, feems to be too little interested in the success of his endeavours, to take much pains in procuring for him the requisite information. Imitations, however, have been made of them, and we have an European tutenag, and an European white coppert, differing, in some qualities, from those which are ne no mobrought

\* Buffon quotes Homer's Odyssey, and some Chinese authors, to prove that the use of the mariner's compass in navigation was known to the ancients, at least three thousand years ago. Nat. Hift. by Buffon, Vol. IX. p. 17. Smellie's Trans.

† The ingenious Dr. Higgins has been honoured by the Society for the Encouragement of Atts, &c. with a gold medal for white copper made with English materials, in imitation of that brought from the East Indies. His process has not, I believe, been yet made public. Mem. of Agricul. Vol. III. p. 459.

brought from Asia, but resembling them in so many other, that they have acquired their names. Something of this kind may have been the case with respect to orichalcum, and the most ancient Greeks may have known no more of the manner in which it was made, than we do of that in which the Chinese prepare their white copper: they may have had too an imitation of the original, and their authors may have often mistaken the one for the other, and thus have introduced an uncertainty and consussion into their accounts of it.

There is as little agreement amongst the learned concerning the etymology of orichalcum, as concerning its origin. Those who write it aurichalcum, suppose that it is an hybridous word, composed of a Greek term fignifying copper, and a Latin one fignifying gold. The most general opinion is, that it ought to be written oricbalcum, and that it is compounded of two Greek words," one fignifying copper, and the other a mountain, and that we rightly render it by, Mountain Copper. I have always looked upon this as a very forced derivation, inafmuch as we do not thereby distinguish orichalcum from any other kind of copper; most copper mines, in every part of the world, being found in mountainous countries. If it should be thought, that some one particular mountain, either in Greece or Afia, formerly produced an ore, which being finelted, yielded a copper of the colour of gold, and that this copper was called orickalcum, or the mountain copper, it is much to be wondered at, that neither the poets nor the philosophers of antiquity have bestowed a single line in its commendation; for as to the Atlantis of Plato, before mentioned, no one, it is conceived, will build an argument for the existence of natural orichalcum, on fuch an uncertain foundation : and, if there had been any fuch mountain, it is probable, that the copper it produced would have retained its name, just as at this time of day, we speak of Etton copper in Stoffordsbire, and of Paris mountain copper in Anglesey. Some

ger made policy. Make the Application Wall Dr. of the great

Some men are fond of etymological inquiries, and to them I would suggest a very different derivation of orichalcum. The Hebrew word or, aur, signifies light, fire, stame; the Latin terms uro to burn, and aurum gold, are derived from it, inasmuch as gold resembles the colour of stame, and hence, it is not improbable, that orichalcum may be composed of an Hebrew, and a Greek term, and that it is rightly rendered stame-coloured copper. In consistantion of this it may be observed, that the Latin epithet lucidum, and the Greek one passes, are both applied to orichalcum by the ancients; but I would be understood to submit this conjecture, with great deserence, to those who are much better skilled than I am in etymological learning.

Of Gun-metal - Statuary-metal - Bell-metal - Pot-metal, and Speculum-metal,

BESIDES brass there are many other metallic mixtures, into which copper enters as the principal ingredient; the most remarkable of these are gun-metal bell-metal pot-metal, and speculam-metal.

It has been remarked of Queen Elizabeth, that she left more brass ordnance at her death, than she found of iron on her accession to the throne. This must not be understood, as if gun-metal was in her time made chiefly of brass; for the term brass, was sometimes used to denote copper, and sometimes a composition of iron, copper, and calamine, was called brass, and we at this day commonly speak of brass cannon, though brass does not enter into the composition used for the casting of cannon. Aldrovandus in-

forms

forms us, that one hundred pounds weight of copper with twelve of tin, made gun-metal; and that, if instead of twelve, twenty pounds weight of tin was used, the metal became bell-metal. The workmen were accustomed to call this composition, metal or bronze, according as a greater or a less proportion of tin had been used. Some individuals, he fays, for the fake of cheapness, used brass or lead instead of tin, and thus formed a kind of bronze for various works. I do not know whether connoisseurs esteem the metal, of which the ancients cast their statues, to be of a quality superior to our modern bronze; but if we should wish to imitate the Romans in this point, Pliny has enabled us to do it; for he has told us, that the metal for their statues, and for the plates on which they engraved inscriptions, was composed in the following manner. They first melted a quantity of copper; into the melted copper, they put a third of its weight of old copper, which had been long in use; to every hundred pounds weight of this mixture, they added twelve pounds and an half of a mixture, composed of equal parts of lead and tin \*.

In Diego Ufano's Artillery, published in 1614, we have an account of the different metallic mixtures then used for the casting of cannon, by the principal gun-founders

in Europe.

Copper 160 - 100 - 100 - 100 parts
Tin 10 - 20 - 8 - 8

The best possible metallic mixture cannot be easily ascertained, as various mixtures may answer equally well the rude purpose to which ordnance is applied. Some mixtures, however, are unquestionably better adapted to this purpose than other, in some particular points. Of two metallic mixtures, which should be equally strong, the lightest would have the preference: at the last siege of Progue,

100 1000

m stress rational r

part of the ordnance of the besiegers, was melted by the frequency of the firing; the mixture of which it was made, contained a large portion of lead, and it would have been less prone to melt, and consequently preferable had it contained none.

Woolwich, I believe, is the only place in England, where there is a foundery for the casting of brass cannon. The metallic composition there used, consists of copper and tin. The proportion, in which these two metals are combined, is not always the same, because the copper is not always of equal purity, and the sinest copper requires the most tin; they seldom use more than 12, or less than 8 parts of tin to every 100 of copper. This metallic mixture is sold, before casting, for 75 f. a ton, and Government pays for casting it 60 f. a ton. The guns of the East India Company are less ornamented than those of Government, on that and other accounts they are cast for 40 f. a ton. I have here put down the weights of the brass ordnance, now most generally in use as cast at Woolwich,

with courtily in nices can at Maniwich. In casting these pieces of cannon, they generally make the thickness of the fides near the muzzle half the diameter of the fhot, and at the touchhole, or charging cylinder, three fourths of the diameter. Brafs cannons are dearer than fuch as are made of iron; and, which is a difadvantage, they give a louder report at the time of explosion, so as to occasion a a tingling in the ears of the perfons on thipboard, which takes away for a time the faculty of hearing.

Cannon might be cast of copper alone; but the mixture of tin and copper is harder and denser, and less liable to rust than pure copper is, and upon these accounts it is preferable to copper. Tin melts with a finall degree of heat, copper requires a very great heat to melt it; a mixture of copper and tin melts much easier than pure copper: and upon this account also, a mixture of copper and tin is perferred to pure copper, not only for the casting of cannon, but of statues, &c.; for pure copper, in running through the various parts

of the moulds, would lose so much of its heat as to set be-

fore it ought to do.

Bell-metal confifts also of tin and copper. Authors do not agree in the proportions: some ordering I part of tin to be melted with 4 parts of copper "; others making the proportion for bell-metal to be the fame as that for gun-metal, or I part of tin to about 10 parts of copper, to which they order a little brass to be added +. It may in general be obferved, that a less proportion of tin is used for making church bells than clock bells, and that they add a little zinc for the bells of repeating watches, and other fmall bells. This zinc becomes manifest on melting these bells, by the blue flame which it exhibits.

There is a very remarkable experiment mentioned by Glauber 1 .- " Make," fays he, " two balls of copper, and two of pure tin not mixed with lead, of one and the fame form and quantity, the weight of which balls observe exactly: which done, again melt the aforefaid balls or bullets into one and first the copper, to which melted add the tin, lest much tin evaporate in the melting, and prefently pour out the mixture melted into the mould of the first balls, and there will not come forth four, nor scarce three balls, the weight of the four balls being referved." This fubject has been profecuted fince Glauber's time f, and it has been discovered. that when metallic substances are melted together, it seldom happens that a cubic inch of each of the two ingredients will form a mass exactly equal to two cubic inches; the mixture will in some instances be greater, and in other less than two cubic inches. In the instance of tin and coppe where the bulk of the mixture is fo much less than the fum of the bulks of the two component parts, it might be exand the bod - charter of the the

<sup>5</sup> Gellert's Chy. Metal. & Chem. Dict. art. Allay.

pected that the compound metal would possess properties, not merely intermediate between those of copper and tin, but essentially different from them both. And accordingly we find, that this mixture is not only more brittle, more hard, and more sonorous, than either copper or tin; but it is more dense also, than either of them; a cubic foot of it weighing, not only more than a cubic foot of tin, but than a

cubic foot of copper itself.

Pot-metal is made of copper and lead, the lead being one fourth or one fifth the weight of the copper. In Pliny's time pot-metal (ollaria temperatura) was made of a pound and an half or two pounds of lead, and an equal portion of tin, mixed with 100 parts of copper. Copper and lead feem not to be combined together in the fame way that copper and tin are, for when pot-metal is exposed to a melting heat, the lead is first fuled, and shews itself in little drops over the surface of the pot-metal, whilst the copper remains unsufuled.

It is reported of James II. that he melted down and coined all the brais guns in Ireland, and afterwards proceeded to coin the pewter with this inscription — Melio is tasserated to coin the pewter with this inscription — Melio is tasserated fati. The Congress in America had recourse to the same expedient; they coined several pieces of about an inch and half in diameter, and of 240 grains in weight; on one side of which was inscribed in a circular ring near the edge — Cantinental Currency, 1776 — and within the ring a rising sunder which was — Mind your business. — On the reverse were thirteen small circles joined together like the rings of a chain, on each of which was inscribed the name of some one of the thirteen states; on another circular ring, within these, was inscribed — American Congress — and in the central space — We are One. — I have been particular in the mention of this piece of money, because like the leaden money which was struck at Vienna, when that city was besieged by the Turks in 1529, it will from become a great curiosity. I estimated the weight of a cubic foot of this Continental

Continental currency, it was equal to 7440 ounces: this exceeds the weight of a cubic foot of our best fort of pewter, and falls short of that of our worst; I conjecture that the metal of the continental currency consisted of 12 parts of tin and of 1 of lead. Plantus , and the other Roman authors make mention of leaden money; fome are of opinion that we ought to understand by that expression, copper mixed with lead; but that cannot be the meaning, if it be true, that the Romans did not mix lead with their copper currency till the age of Septimius Severus, for Plantus lived many years before that emperor. I will not enter into the controverfy, and I have introduced this observation relative to the leaden money of the Romans, merely to shew the correspondence, which fome of the Roman copper medals bore to our pot-metal, for those which were struck after the age of Septimius Severus, being exposed to a proper degree of heat, fweat out drops of lead, as it has been remarked our pot-metal does: but medals of greater antiquity have no fuch property f. claims and a little firm to min

These pot-metal medals were probably cast.

1 Sat. 2. l. 102.

Homer, in describing June at her toilet \*, makes no mention of a speculum; but in Callimachus + we see, though it fuited not the majesty of Juno, nor the wisdom of Pallas, to use a speculum before they exhibited their persons to Paris, who was to determine the prize of beauty; that Venus, on the fame occasion, had frequent recourse to one, before she could adjust her locks to her own fatisfaction. The most ancient account we have of the use of specula, is that in Exedus (xxxviii. 8.) " And he made the laver of brafs [copper, or a mixture of copper and tin] and the foot of it of brafs of the looking-glaffes of the women." The English reader may wonder how a vessel of brass could be made out of looking glasses, the Hebrew word might properly be rendered by specula or metallie mirrors. The Jewish women were, probably, prefented with these mirrors, as they were with other articles of value by their Egyptian neighbours, when they left the country; for it was the cultom of the Egyptians, when they went to their temples, to carry a mirror in their left hand t : it is remarkable, that the Porte vians, who had so many customs in common with the Egyptians, were very fond also of mirrors; which they ordinarily formed of a fort of lava that bord a fine polith. and side

Pliny fays, that the best specula were anciently made at Brundusium of copper and tin ; that Praviteles, in the time of Pompey the Great, was the first who made one of filver, but that filver ones were in his time become fo common, that they were used even by the maid-servants. 'The. metallic mixture of tin and copper was known long before the age of Pliny; it is mentioned by Aristotle I, incidentally, when he is describing a method of rendering copper white, but not by tin; and from its great utility, it will probably never fall into difuse. We have ceased, indeed,

-lound the damping many to the Abulgardence fince

mela molt senem Severi enfor quipo es quibes 1 Cyril. de Ado. 5 Hift. Nat. L. XXXIII. S. XLV. ¶ De Mirab.

fince the introduction of glass mirrors, to use it in the way the antients did; but it is still of great use amongst us, fince the specula of reflecting telescopes are commonly made of it. Mr. Mudge has afcertained , not only the best proportion in which the copper and tin should be mixed together, but has found out also a method of casting the specula without pores. He observes, that the perfection of the metal, of which the speculum should be made, consists in its hardness, whiteness, and compactness. When the quantity of tin is a third of the whole composition, the en has its utmost whiteness; but it is at the same rendered fo hard that it cannot be polished without having Its furface splintered and broke up. After many onts, he at length found that fourteen ounces and one half of grain-tin +, and two pounds of the best composition; an addition of half an ounce more the best composition; an addition of half an ounce more hard to be properly polished. tin rendered the composition too hard to be properly polished. The calling the metal fo as that it may be compact and without pures, is a matter of the greatest consequence; he hit upon the manner of doing it by accident. His usual way of casting a speculum metal, was to melt the copper and to add the tin to the melted copper; the mass when cast was feldom free from pores. After having used all his copper in trying experiments to remedy this defect, he recollected that he had some metal which had been reserved, when one of the bells of St. Andrew had been re-cast: he added a a little fresh tin to it, and casting a metal with it, it turned Vot. II.d Men Charles to If a second out

\* Philof, Tranf. 1777. p. 296.

† "Grain-tin is worth ten or twelve shhillings per hundred more than mine tin, because it is smelted from a pure mineral by a charcoal fire; whereas mine tin is usually corrupted with some portion of mundick, and other minerals, and is always smelted with a bituminous fire, which communicates a harsh, sulphureous, injurious quality to the metal." Pryce, Min. Cornu p. 137.—Mr. Mudge probably used what is called grain tin in the shops, or the purest fort, which is usually sold in pieces like icicles.

considerates of the that the still the commenced

out free from pores, and in all respects as fine a metal as he ever faw. Upon confidering this circumstance, he proceeded to form a metallic mass in the usual way, by adding tin to melted copper, this mass was porous, it was in the state of the bell-metal he had tried, and upon remelting it, it became, as the bell-metal had done, compact and free from pores. He accounts for this difference by observing, that the heat necessary to melt copper, calcines part of the tin, and the earthy calcined particles of the tin, being mixed in the mass of the metal, render it porous, but the composition of tin and copper, melting with less than half the heat requifite to melt the copper, the tin is not liable to be calcined in the fecond melting, as in the first. I am rather disposed to think, that the absence of the pores is to be attributed to the more perfect fusion of the metal : for I have observed at Sheffield, that the same weight of melted steel, will fill the fame mould to a greater-or less height, according to the degree of fusion the steel has been in; if it has been in a strong heat, and thin fusion, the bar of cast steel will be an inch in 36 shorter than when the fusion has been less perfect. Upon breaking one of the bars, which had been made from steel in an imperfect fusion, its inside was full of blebs; a shorter bar of the same weight and diameter, which had been in a thin fusion, was of a closer texture. Now the mixture of tin and copper melts far eafier than copper does, and is likely on that account, to be in a thinner fusion when it is cast.

It may deserve to be remarked, and I shall have no other opportunity of doing it, that the melting or cashing of steel was introduced at Shessield, about forty years ago, by one Waller from London, and was afterwards much practised by one Hunssman, from whom sheel so prepared, acquired the name of Hunssman east steel. It was at first sold for fourteen-pence, but may now be had for ten-pence a pound; it costs three-pence a pound in being melted, and for drawing ingots of cast steel into bars of the size of raiors, they pay

pay only fix shillings for a hundred weight, and ten shillings for the same quantity when they make the bars into a size sit for small siles, &c. The cast steel will not bear more than a red heat, in a welding heat it runs away under the hammer like sand. Before the art of casting steel was introduced at Shossield, all the cast steel used in the kingdom was brought from Germany; the business is carried on at Shossield with greater advantage, than at most other places, for their manufactures surnish them with great abundance of broken tools, and these bits of old steel they purchase at a penny a pound and melt them, and on that account they can afford their cast steel cheaper than where it is made altogether from fresh bars of steel.

## I palianos E S S. A. Y. XXXII.

# to enciron and encircle frederice, in noviers of the feet of the feet of the feet of the feet of the charters and the charters of the charters.

NHAPPILY for mankind, the fatal accidents attending the use of copper vessels, in the preparation of food and physic, are too common and too well attested to require a particular enumeration or proof: scarce a year passes, but we hear of some of them, especially in foreign countries; and many slighter maladies, originating from the same fource, daily lescape observation, or are reserved to other causes in our own.

In consequence of some representations from the College of Health, the use of copper vessels in the seets and armies of Sweden was abolished in the year 1754; and tinned iron was ordered to be substituted in their stead. The Swedish government deserves the greater commendation for I i 2

Mem, de l' Acad. de Pruffe par M. Paul. Vol. IV. Dif. Prel. p. 63.

this proceeding, as they have great plenty of excellent copper in the mines of that country, but no tin. An intelligent furgeon fuggested, in 1757, the probability of the use of copper vessels in the navy, being one of the causes of the sea scurvy, and recommended the having them changed for velfels of iron; he remarked, that of the 200 fail of thips which went to fea from Searborough, most of them used iron pots for boiling their victuals, and that the fymptoms called highly feorbutic, were never feen, except in some few of the larger ships in which copper veffels were used . Notwithstanding this hint, and the example of Sweden, I do not know that any other European state has prohibited the use of copper vessels for the dreffing of food on board their ships; but many of them have shewn a laudable attention to prevent its malignity; by inquiring into the best manner of covering its furface with fome metallic fubstance, less noxious, or less liable to be dissolved than itself. This operation is usually called tinning, because tin is the principal ingredient in the metallic mixture, which is made use of for that purpofe; and, indeed, fince the year 1755, it has been frequently, in this country at least, used alone. In that year, The Society for the Encouragement of Arts, manufactures and Commerce, thought it an object deserving their attention, to offer a premium for the tinning copper and brass vessels with pure tin, without lead or any other alloy. There were feveral candidates for the premium; and fince that time, the tinning with pure tin, and hammering it upon the copper, has become very general in England. But this mode of tinning does not appear to have been known, or at least it does not appear to have been adopted in other countries; for in the Memoirs of the Royal Academy at Bruffels, for the year 1780, M. L'Abbe Marci recommends, as a new practice, the tinning with pure block-tin

Medical Obser. by a Society of Phy. in Lond. Vol. II.

block-tin from England; though, he fays, block tin is a compound body, even as it is imported from England; but he thinks it a much fafer covering for copper than what is ordinarily used by the braziers; and he gives some directions as to the manner of performing the operation. The Lieutenant-General of the Police in Paris, gave it in commission to the College of Pharmacy, in 1781, to make all the experiments which might be necessary for determining whether pure tin might or might not be used for domestic purposes, without danger to health? The refearches which were made, in confequence of this commission, by Messieurs Charland and Bayen with great ability, were published by order of the French government; and they have greatly contributed to lessen the apprehensions relative to the use of tin, which had been generally excited by the experiments of Marggraf, published first in the Berlin Memoirs for 1747. That gentleman, in pursuing an experiment of Henckel, who first discovered arfenic in tin, shewed, that though there was a fort of tin, which being fluxed from an ore of a particular kind, contained no arfenic, the East India tin, which is generally esteemed the purest of all others, contained a great deal of arfenic. M. Bosc'd' Antic in his works, which were published at Paris, 1780, sets aside the authority of Marggraf, Cramer, and Hellot, relative to the existence of arfenic in tin; and is not only of opinion, that the Cornist tin does not conceal any arsenic in its substance, but that its use as kitchen furniture is not dangerous. Meffieurs Charland and Bayen found that neither East India, nor the purest fort of English tin, contained any arfenic; but that the English tin, usually met with in commerce, did contain arfenic; though in fo fmall a proportion that it did not amount, in that species of tin which contained the most of it, to more than one grain in an ounce; that is, it did not constitute more than one five-hundredth and seventy-fixth part of the weight of the tin, there being II3 579

576 grains in a French ounce. This proportion of arfenic is fo wholly inconfiderable, that it is very properly concluded, that the internal use of such small portions of tin, as can mix themselves with our food, from being prepared in tinned veffels, can be in no fenfible degree dangerous on account of the arfenic which the tin may contain. But though tin may not be noxious, on account of the arfenic which it holds, it still remains to be decided, whether it may not be poisonous of itself; as lead is univerfally allowed to be, when taken into the stomach. The large quantities of tin, which are sometimes given in medicine with much fafety, and the constant use which our ancestors made of it in plates and diffies, before the introduction of china or other earthen ware, without experiencing any mischief, render all other proof of the innocent nature of pure tin superfluous. And hence it may be proper to add a few observations concerning the purity of tin.

The ores of metallic fubitances, often contain more fubstances than that particular one, from which they receive their denomination. M. Eller of Berlin, had in his collection an ore, which contained gold, and filver, and iron, and quickfilver, closely united together in the fame mass. Lead ore, it has been remarked, so often contains filver, that it is feldom found without it; it is often also mixed with a fulphureous pyrites, which is a fort of iron ore, and with black jack, which is an ore of zinc; fo that lead, and filver, and iron, and zinc, are commonly enough to be met with in the same lump of lead ore. Tin ore, in like manner, though it is fometimes unmixed, is often otherwise; it frequently contains both tin, and iron, and copper. The fire with which tin ore is fmelted, is fufficiently strong to smelt the ores of the other metals which are mixed with it; and hence the reader may understand, that, without any fraudulent proceeding in the tin finelter, there may be a variety in the purity of tin, which is exposed to

fale in the fame country; and this variety is still more likely to take place, in specimens of tin from different countries, as from the East Indies, from England, and from Germany. This natural variety in the purity of tin, though fufficiently discernible, is far less than that which is fraudulently introduced. Tin is above five times as dear as lead a and as a mixture confisting of a large portion of tin with a finall one of lead, cannot eafily be diffinguished from a mass of pure tin; the temptation to adulterate tin is great, and the fear of detection finall. In Cornwall, the purity of tin is afcertained, before it is exposed to fale, by what is called its coinage: the tin, when finelted from the ore, is poured into quadrangular moulds of stone, containing about 320 pounds weight of metal, which, when hardened, is called a block of tin; each block of tin is coined in the following manner:-" the officers appointed by the Duke of Cornwall, affay it, by taking off a piece of one of the under corners of the block, partly by cutting and partly by breaking; and if well purified, they stamp the face of the block with the impression of the seal of the Duchy, which stamp is a permission for the owner to fell, and at the same time an affurance that the tin fo marked has been purposely examined, and found merchantable"." This rude mode of affay, is not wholly improper, for if the tin be mixed with lead, the lead will by its fuperior weight fink to the bottom, and thus be liable to be discovered, when the bottom corner of the block is examined. But though the feal of the Duchy may be some security to the original purchasers of block tin, it can be none at all to those foreigners who purchase our tin from Holland; for, if we may believe an author of great note,-" in Holland every tin founder has English stamps, and whatever his tin be, the inscription, block tin, makes it pass for English +." This foreign adul-

<sup>\*</sup> Borlase's Nat. Hift, of Corn. p. 183.

<sup>†</sup> Newman's Chem. by Lewis, p. 89.

teration of English tin may be the reason that Musselenbrocch, who was many years Professor of Natural Philosophy at Utretch, puts the specific gravity of what he calls pure tin equal to 7320, but that of English tin, and he has been followed by Wallerius, equal to 7471\*; for it will appear presently, that such sort of tin must have contained near one tenth of its weight of lead.

Weight of a cubic foot of English tin, according to dif-

ferent authors.

Musschenbroeck & Wallerius 7471
Martin - 7550

From the following experiments it may appear probable, that not one of these authors, in estimating the specific gravity of tin, has used the purest fort, but rather a mixture

of that with lead, or fome other metal.

A block of tin, when it is heated till it is near melting, or after being melted, and before it becomes quite fixed, is so brittle that it may be shattered into a great many long pieces like icicles, by a smart blow of an hammer †: tin in this form is called by our own manufacturers grain tin, by foreigners virgin tin, or tears of tin: and they tell us, that its exportation from Britain is prohibited under pain of death

Musschen, Est. de Phys. 1739. French Trans. Wallerii Min. Vol. I. p. 154. There is a very good Table of Specific Gravities, published in the second volume of Musschenbroek's Introduction and Philosophiam Naturaless, 1763, in which the author does more justice to English tin, putting the weight of a cubic foot of the purest fort equal to 7295 avoir. oun. One specimen of the purest fort of Malacca tin gave 7331, and another 6125 ounces a cubic foot, which is the lightest of all the tins which he examined.

<sup>†</sup> This property is not peculiar to tin. I have feen maffes of lead which, under fimilar circumftances, exhibited fimilar appearances, and it has been observed, that zinc, when heated till it is just ready to be fused, is brittle.

death. The tin, which I used in the following experiments, was of this sort, but I first melted it, and let it cool gradually; a circumstance, I suspect, of some consequence in determining the specific gravity not only of tin, but of other metals. I have put down in the following table, the specific gravity of this tin, and of the lead I mixed with it by susion, and of the several mixtures when quite cold; the water in which they were weighed was 60°.

Blocks of tin are often melted by the pewterers into finall rods; I think the rods are not so pure, as the grain tin; at least, I found that a cubic foot of the specimen I examined, weighed 7246 ounces; but even this fort exceeds in purity any of the kinds examined by the authors above mentioned. Chemistry affords certain methods of discovering the quantity of lead with which tin is alloyed, but these methods are often troublesome in the application; an enlarged table, of the kind of which I have here given a specimen, will enable us to judge with sufficient precision of the quantity of lead contained in any mixture of tin and

the war at many work to compare the total of the contract

Eney Fran. and Mr. Baumé calls it étain en roche à cause que sa some resemble à des stalactites; he says also, that its exportation is prohibited, but that he does not see the reason for the prohibition, as it is not more pure than Cornish tin: and in this observation he is right, it is nothing but Cornish tin in a particular form. Chym. par M. Baumé, Vol. III. p. 422.

lead, of which we know the specific gravity. Pewterers, however, and other dealers in tin, use not so accurate a method of judging of its purity, but one founded on the fame principle; for the specific gravities of bodies being nothing but the weights of equal bulks of them, they cast a bullet of pure tin, and another of the mixture of tin and lead, which they want to examine, in the fame mould; and the more the bullet of the mixture exceeds the bullet of pure tin in

weight, the more lead they conclude it contains.

Pewter is a mixed metal; it confifts of tin united to fmall portions of other metallic fubstances, such as lead, zinc, bifmuth, and the metallic part, commonly called, regulus of antimony. We have three forts of pewter in common use; they are distinguished by the names of plate trifle - leg. The plate pewter is used for plates and diffies; the trifle chiefly for pints and quarts; and the leymetal for wine measures, &c. Our very best fort of pewter is faid so confilt of 100 parts of tin, and of 17 of regulus of antimony, though others allow only 10 parts of regulas to roo of tin+; to this composition the French add a little copper. Crude antimony, which confifts of nearly equal portions of fulphur and of a metallic fubiliance, may be taken inwardly with great fafety; but the metallic part, or regulus, when separated from the sulphur, is held to be yery polionous. Yet plate pewter may be a very innocent metal, the tin may leffen or annihilate the noxious qualities of the metallic part of the antimony. We have an instance fomewhat similar to this in standard filver, the use of which has never been efteemed unwholfome, notwithstanding it contains near one twelfth of its weight of copper. Though standard filver has always been confidered as a fafe metal, when used for culinary purposes; yet it is not altogether so, the copper it contains is liable to be corroded by faline fubstances into virdigris. This is frequently feen, when common fair is suffered to stay a few days in silver saltcellars,

<sup>\*</sup> Med. Tranf. Vol. I p. 286. + Pemb. Chem. p. 322.

which have not a gold gilding; and even faline draughts, made with volatile falt and juice of lemons, have been observed to corrode a filver tea spoon, which had been left a work in the mixture.

The weight of a cubic foot of each of these forts of

Plate - 7248
Trifle - 7359
Lev - 7963

If the plate pewter be composed of tin and regulus of antimony, there is no reason to expect, that a cubic foot of it should be heavier than it appears to be; since regulus of entimony, according to the different ways in which it is made, is heavier or lighter than pure tin. A very fine filverking metal is faid to be composed of 100 pounds of tin, 8 of regulus of antimony, 1 of bifmuth, and 4 of copper. The ley pewter, if we may judge of its composition by comparing its weight with the weights of the mixtures of tin and lead, mentioned in the table, contains not fo much as a third, but more than a fifth part of its weight of lead; this quantity of lead is far too much confidering one of the nies to which this fort of pewter is applied; for acid wines will readily corrode the lead of the flagons, in which they are measured, into sugar of lead; this danger is not so great with us, where wine is feldom fold by the measure, as it is in other countries where it is generally fold fo, and eir wine measures contain, probably, more lead than ours do. Our English pewterers have at all times made a mystery of their art, and their caution was formerly fo much encouraged by the legislature, that an act of parliament was passed, rendering it unlawful for any master pewterer to take an apprentice, or to employ a journeyman who was a foreigner. In the present improved state of chemistry, this caution is ufeless; fince any one tolerably skilled in that science, would be able to discover the quality, and quantity of the metallic fubstances, used in any particular fort of pewter; and it is not only useless now, but one would have thought thought it must have been always so; whilst tin, the principal ingredient, was found in no part of Europe in so pure a state, nor in so great plenty as in England.

Borlase and Pryce, who have written so minutely on the method of preparing the tin in Cornwall, are both of them filent, as to any operation the tin undergoes fublequent to its coinage; nor do they fay any thing of its being mixed with other metallic fubstances previous to its coinage; but affure us, that the tin, as it flows from the ore. is laded into troughs, each of which contains about three hundred pounds weight of metal, called flabs, blocks, or pieces of tin, in which fine and form it is fold in every market in Europe. Foreigners, however, in general affert, that our tin as exported is a mixed metal; and the French Encyclopediffs in particular (article etain) inform us, on the authority of Mr. Rouelle, that the virgin tin is again melted and cast into iron moulds of half a foot in thickness; that the metal is cooled very flowly; that when cold it is divided horizontally into three layers; that the uppermost, being very foft pure tin, is afterwards mixed with copper, in the proportion of 3 pounds of copper to 100 of tin; that the fecond layer, being of a harsher nature, has g pounds of lead added to an soo of the tin; and that the lowest layer is mixed with 9 pounds of lead to an hundred of the tin; the whole is then re-melted, and cooled quickly, and this, they fay, is the ordinary tin of England; and Geoffroy had formerly given much the fame account . There is, probably, no other foundation for this report,

<sup>\* —</sup> fusores aperto furni ostiolo, metallum in formas quasdam ex arena paratas diffluere sinunt, ibique in massas grandiores concrescit. Superior stannæ massæ pars adeo mollis est et stexilis ut tola elaborari nequeat sine cupri miscela, trium scilicet librarum super stanni libras centum. Massæ pars media binas tantum eupri libras recipit. Insima vero adeo fragilis est et intractabilis, ut cum hujus metalli centum libris plumbi libras octodecim consociare oporteat. Geoss. Mat. Med. Vol. I. p. 282.

but that pewter has been mistaken for tin, these metals being fometimes called by the same name; and fine pewter being fometimes made from a mixture of 1 part of copper with 20 or 30 parts of tip.

The mixture generally used for the tinning of copper vesfels, confilts of a pounds of lead, and of 5 pounds of pewter; when a finer composition is required, ten parts of lead are mixed with fixteen of tin; or one part of lead with two of tin; but the proportions in which lead and tin are mixed together, even for the same kind of work, are not every where the fame; different artifts having different customs. Vellels tinned with pure tin, or with the best kind of pewter, which contains no lead, do not stain the fingers when rubbed with them; whill those which are tinned with a compofition, into which lead enters as a constituent part, colour the fingers with a blackish tinge.

Zinc was long ago recommended for the tinning of copper veffels, in preference both to the mixture of tin and lead, and to pure tin \* : and zinc certainly has the advantage of being harder than fin, and of bearing a greater degree of heat before it will be melted from the furface of the copper fo that on both these accounts it would, when applied on the furface of copper, last longer than tin, just as tin, for the same reasons, lasts longer than a mixture of tin and lead. But whether zinc makes any part of the compound metal for tinning copper, fo as to prevent the necessity of repeated tinning, for which a patent was granted fome years ago, is what I cannot affirm. Whatever may be the excellence of that composition, or of any other composition, which may be invented with respect to its durability, and its not contracting ruft; still it ought not to be admitted into general ufe, till it has been proved, that it is not foluble in vegetable acids, or that its folutions are not noxious +. A method

Mem. de l' Acad. des Scien. a Par. 1742.

This doubt with respect to zinc is faid to have been removed. M. de la Planche, a physician at Paris, tried the experiment nos les me che Decent, de

has of late years been introduced at Rouen, of applying coat of zinc upon bammered iron faucepans. The vent are first made very bright, so that not a black speck can feen; they are then rubbed with a folution of fal and and afterwards dipped into an iron pot full of melte and being taken out, the zinc is found to cover the furth of the iron; and if a thicker coat of zine is wanted, it may be obtained by dipping the veffel a fecond time. This is of covering is fo hard, that the vellels may be foured wit fand without its being rubbed off . Kitchen utenfil which are made of cast iron, are usually tinned to preve the iron's rufting; and, as great improvements have been lately made in rendering cast iron malleable, it is not unlike ly, but that tinned iron vessels may become of general use.

The common method of tinning, confilts in making turface of the copper vellel quite bright, by scraping it by washing it with a solution of fall ammoniae: It is the heated, and the tin, or metallic mixture designed for tinning is melted, and poured into it, and being made quickly to flow over every part of the furface of the veilel, it incorpor rates with the copper, and when cold, remains united it. Rolin or pitch are sometimes used, to prevent the time from being calcined, and the copper from being scaled, cithe of which circumstances would hinder the sticking of the tin-

I had the cariolity to effimate the quantity of pure tin which is used in tinning a definite surface of copper. The veffel was accurately weighed before and after it was to its furface was equal to 254 square inches; its weight, b fore it was tinned, was 46 ounces, and its weight, at operation, was barely 461 ounces; so that half an o

on himself: he took the salts of zinc, formed by the vege acids, in a much stronger dose than the aliments prepared in to per vessels, lined with zinc, could have contained, and he fall dangerous effects from them. Fourcroy's Chem. Vol. I. p. 449. Journ. de Phy. Decem. 1778.

content to follow and that bostops

tin was foread over 254 fquare inches, or fomewhat lefs than a grain of tin upon each fquare inch. How innocent foever pure tin may be, yet the tenuity of the coat of it, by which copper veffels are covered, in the ordinary way of tinning, cannot fail to excite the ferious apprehentions of those who consider it; for in the experiment which I have mentioned, the tin was laid on with a thicker coat than in the common way; inflead of a grain, I fuspect that not a quarter of a grain of tin is spread over a square inch in the common way of tinning. A discovery has been lately made at Paris of a method of giving to copper or iron a coat of any required thickness, by tinning them; the compolition used for the tinning is not mentioned, but it is faid that a piece of copper, which in the common way of tinning only absorbed 21 grains of tin, absorbed of the new compolition 442 grains, or above twenty times as much . Till this discovery is generally known, our workmen should study to cover the copper with as thick a coat as they are able of pure tin. The danger from the corresion or folution of the tin by vinegar, juice of lemons, or other vegetable acids, if any at all, cannot, it is apprehended, be fenfibly felt, except in very irritable habits, or where four broths, fances, or fyrups are fuffered to stand long in tinned veffels before they are used. And, indeed, a proper attention to keeping the veffels clean, might render the use of copper itself, for the boiling of food, especially of animal food, wholly lafe. The French may be allowed to excel us in cookery, but we probably excel them in cleanlines; for the melancholy accidents attending the use of copper vessels, are much less frequent in England than in France; and this difference proceeds; I conjecture, from the superior care of the English in keeping their vessels clean, and from the cheapness and purity of the tin we use in tinning copper We are not certain that the art tinning copper veilels was known to the Yews, when they came out of

L' Esprit des Journaux, Mai, 1785.

Egypt; the vessels used in the temple service, were made of copper by divine appointment; and by being constantly kept clean, no inconveniences followed. The wort, from which malt liquor is brewed, is boiled in copper vessels; the distillers and consectioners, prepare their spirits and syrups in un-tinned vessels of the same metal, without our suffering any thing in our health from these practices; at least, without our being generally persuaded that we suffer any thing. A new copper vessel, or a copper vessel newly tinned, is more dangerous than after it has been used; because its pores, which the eye cannot distinguish, get filled up with the substances which are boiled in it, and all the sharp edges of the prominent parts become blunted; and are

thereby rendered less liable to be abraded.

M. de la Lande, in describing the cabinet at Portici, observes, that the kitchen utenfils, which have been dug up at Herculaneum, are almost all of them made of a compound metal like our bronze, and that many of the veffels are covered with filver but none of them with tin: and hence he concludes, that the useful art of applying tin upon copper, was unknown to the Romans; cet art utile d'appliquer l' etain fur le cuivre manquoit aux Romains . By the fame mode of arguing, it might be inferred, that whatever is not met with in one honse or town, is not to be found in a whole country: yet, should a town in England, in which there happened to be plenty of tinned, but no plated or filvered copper, be fwallowed up by an earthquake, a future antiquary, employed in digging up its ruins, would make a bad conclusion, if he should thence infer, that the English understood, indeed, at that time the art of applying a covering of tin, but not one of filver upon copper. If the ingenious author had recollected what is faid in the 34th book of Pliny's Natural History, he would have feen reason to believe, that the Romans, at least when Pliny wrote that book, did understand the method of tinning copper which is now

<sup>\*</sup> Voyage d' un Francois en Italie, Vol. VII. p. 120.

in use; for this great naturalist assures us in express terms. that tin fineared upon copper vessels, rendered the taste more agreeable, and restrained the virulence of the copper rust. It is to no purpose to object, that the tin (stannum) of Pliny, was a substance different from our tin; for though it should be in some measure granted, that it was a mixture of lead and filver, yet the fame author tells us, in the fame place, that white lead (plumbum album), by which it is univerfally allowed our tin is meant, was fo incorporated with copper by boiling, that the copper could fcarcely be diffinguished from filver . Nay, it appears that the Romans not only used pure tin, but the same mixture of tin and lead, which fome of our workmen use at this time in tinning vessels. A mixture of equal parts of tin and lead, they called argentarium; a mixture of two parts of lead and one of tin, they call tertiarium; and with equal parts of tertiarium and tin, that is, with two parts of tin and one of lead, they tinned whatever veffels they thought fit. They, moreover, applied filver upon copper, in the fame way in which they applied tin upon it+; and they used this filvered coppe: (I do not call it plated, because copper is plated by a different process) in ornamenting their carriages, and the harness of their horses, as we now use plated copper; on this head Pliny observes, VOL. II.

<sup>\*</sup> Stannum illitum æneis vasis, saporem gratiorem reddit, et compescit æruginis virus, mirumque, pondus non auget—from the weight of the copper not being sensibly increased (for Pliny here speaks popularly) we may infer, that the covering of tin which the copper received was very slight, and the art alluded to by Pliny in this place, was probably the same with that of tinning now in use—album (scil. plumbum) incoquitur æries operibus, Galliarum invento, ita ut vix discerni possit ab argento, eaque incoctilia vocant. This description seems to be expressive of the manner of tinning, by putting the copper into melted tin, as is practised in the tinning of iron plates. Plin, Hist. Nat. L. XXXIV. S. XLIII.

<sup>† —</sup> deinde et argentum incoquere simili modo cœpere equorum maxime ornamentis, &c. Id. ib.

observes, and a rigid philosopher will apply the observation to ourselves, that such was the luxury of the Romans, that it was then simply reckoned a place of elegante to consume in the ornaments of coaches, and in the trappings of horses, metals, which their ancestors could not use in drinking vessels, without being associated at their own prodigality si we are not yet, however, arrived at the extravaguace of Nero and his wife, who shod their favourite horses with gold and filvers their bearacquois of any attention and man bearage.

Pliny mentions an experiment as characteristic of tinthat when melted and poured upon paper, it seemed to
break the paper by its weight, rather than by its heat; and
Aristotle, long before Pliny, had remarked the small degree of heat which was requisite to fuse Celtic (British)
tin . This metal melts with less heat than any other simple metallic substance, except quicksilver; it requiring for
its sustance of the heat in which water boils; but compositions of tin and lead, which are used in tinning, melt
with a still less degree of heat; than what is requisite to
melt simple tin; and a mixture composed of g parts of lead,
g of tin; and 8 of bissouth, though solid in the heat of
the atmosphere, melts with a less degree of heat, than that
in which water boils.

## ESSAY XXXIII.

Of tinning Iron.—Of plating, and gilding Copper.

IRON is tinned in a different manner from copper. In fome foreign countries, particularly in France, Bohemia, and Sweden, the iron plates, which are to be tinned, are put under a heavy hammer which gives, in fome works, 76 strokes

firokes in a minute: they can in one week, with one hammer, fabricate 4320 plates, the iron is heated in a furnace. eight times, and put eight times under the hammer during the operation, and it lofes hear an eighth part of its weight. pper are both of them very apt to be fealed by being heated, and they thereby lose greatly of their weight. Twenty-four hundred weight of pure plate copper, will not, when manufactured into rea-kettles, pans, Sec. give above twenty three handred weight. Twenty-one hundred weight of bar iron will give a ton, when split into rods, but taking into confideration all iron and freel wares, from a needle to an anchor, it is estimated that thirty hundred of bar iron will, at an average, yield a ton of wares .. Thirty hundred weight of cast iron is reduced to twenty, when it is to be made into wire; and twenty-fix to twentytwo, when it is to be made into bar iron. Steel fuffers a much lefs lofs of weight in being hammered, than iron does. Caff fleel does not lose above two parts, and bar steel not above four in 100, when drawn into the shape of rafors, files, &c. The iron plates in England, are not hammered, but rolled to proper dimensions by being put between two cylinders of cast iron cased with steel. This method of rolling iron is practifed in Norway, when they form the plates with which they cover their houses; but whether it was invented by the English, or borrowed from fome other country, (as many of our inventions in metallurgy have been, especially from Germany,) I have not been able to learn. In the first account which I have feen of its being practifed in England, it is faid to have been an invention of Major Hanbury at Pontypool, the account was written in 1607, and many plates had then been rolled t. The milling of lead, however, which is an operation of the fame kind, had been practifed in the year 1670; for an 26

+ Phil. Tranf. Ab. Wol. V.

<sup>\*</sup> See an instructive pamphlet, intitled, A Reply to Sir L. O'Brien, by W. Gibbons, 1785.

aft of parliament was paffed in that year, granting unto Sir Philip Howard, and Reducio Watfon, Efq; the fole use of the manufacture of milled lead, for the theathing of thips. A book was published in 1691; intitled, The new Invention of Milled-Lead for Beathing of Ships, &c. It appears from this book, that about 20 thips, belonging to the navy, had been sheathed with lead; but the practice was discontinued, on account of the complaints of the officers of the navy, that the rudder irons and bolts under water, had been walted to fuch a degree, and in fo short a foace of time, as had never been observed upon any unbeathed or wood-beathed bips. The persons then interested in sheathing with lead, published a sensible defence; and amongst other things, they remarked, that both the Dutch and English had ever been in the habit of sheathing the stern posts and the beards of the rudders with lead or copper; and that the Portuguese and Spaniards did then sheath the whole bodies of their thips, even of their gallions. with lead, and had done it for many years. Copper fheathing has fince taken place in the navy, but it is faid to be liable to the same objections which were, above a century ago, made to lead sheathing. It is preferable, however, to lead, on account of its lightness. If the fact should be once well established, that ships sheathed with lead or copper, will not last so long as those which are unsheathed, or sheathed only with wood; it would be a problem well deferving the confideration of chemists, to inquire into the manner how a metallic covering operates in injuring the construction of the ships, and whether that operation is exerted on the iron bolts, or on the timbers of the ship. When the iron plates have been either hammered or rolled to a proper thickness, they are steeped in an acid liquor, which is produced from the fermentation of barley meal, though any other weak acid would answer the purpose: this steeping, and a subsequent scouring, cleans the furface of the iron from every speck of rust or blackness, the least of which would hinder the tin from sticking

to the iron, fince no metal will combine itself with any earth, and rust is the earth of iron. After the plates have been made quite bright, they are put into an iron pot filled with melted tin; the furface of the melted tin is kept covered with fuet or pitch, or some fat substance, to prevent it from being calcined; the tin presently unites itself to the iron, covering each fide of every plate with a thin white coat; the plates are then taken out of the melted tin, and undergoing fome further operations, which render them more neat and faleable, but are not essential to the purpose of tinning them, they are packed up in boxes, and are every where to be met with in commerce under the name of tin-plates; though the principal part of their fubstance is iron, and hence the French have called them fer blanc, or white iron: Sir John Pettus fays, that they were with us vulgarly called latten; though that word more usually I think denoted brafs.

Tin is not, but iron is liable to contract ruft by exposure to air and moisture, and hence the chief use of tinning iron, is to hinder it from becoming rufty; and it is a question of some importance, whether iron of a greater thickness than the plates we have been speaking of, might not be advantageously tinned. I defired a workman to break off the end of a large pair of pincers, which had been long used in taking the plates out of the melted tin; the iron of the pincers feemed to have been penetrated through its whole substance by the tin; it was of a white colour, and had preferved its malleability. It is usual to cover iron stirrups, buckles, and bridle bits, with a coat of tin, by dipping them, after they are made, into melted tin; and pins, which are made of copper wire, are whitened, by being boiled for a long time with granulated tin in a lie made of alum and tartar. Would the iron bolts, used in ship building, be preserved from rusting by being long boiled in melted tin?-Would it be possible to filver iron plates by substituting melted filver for melted tin? I do not know that this experiment has ever been tried; but an intelligent Kk3

terifieest

telligent manufacturer will fee many advantages which would attend the fuccess of it.

It is coftomary, in fome places, to alloy the tin, used for tinning iron plates, with about one feventieth part of its weight of copper; foreigners make a great fecret of this practice; I do not know whether any of our manufacturers use copper, some of them I have reason to believe do not. Too much copper renders the plates of a blackish hue, and if there is too little, the tin is too thick upon the plates; but this thickness, though it may render the plates dearer or the profit of the manufacturer lefs, will make them laft longer. When the tin is heated to too great a pitch, fome of the plates have yellowish spots on them; but the coat of tin is thinner, and more even, when the tin is of a great, than of a moderate heat; and the yellowness may be taken away, by boiling the plates for two or three minutes in lees of wine, or, where they cannot be had, four small beer, or other similar liquors, may, probably, be used with the fame fuccess. The quantity of tin used in tinning a definite number of plates, each of a definite fize, is not the fame at different manufactories. In some fabrics in Bohemia, they afe 14 pounds weight of tin for making 300 plates, each of them being 114 inches long by 81 broad; according to this account, one pound of tin covers a furface of 283 fquare feet: in other, where the tin is laid on thicker, one pound will not cover above 22 square feet; the thickness of the tin, even in this case, is small, not much exceeding the one thousandth part of an inch; though that is near twice the thickness which tin has upon copper in the ordinary way of tinning. I have inquired of our English manufacturers concerning the quantity, of tin used by them in covering a definite furface of iron, and from what I could collect, it is very nearly the fame with that used in Bohemia, from whence we derived the art of tinning, or 28 fquare feet to a pound of tin.

There are various tin plate manufactories established of late years in different parts of England and Wales. Sano-

2 4 7

ny, and part of Bohemia, formerly supplied all the known world with this commodity; but England now exports large quantities of it to Holland, Flanders, France, Spain, Italy, and other places. About the year 1670, Andrew Yarranton (he deserves a statue for the attempt) undertook. at the expence of some enterprising persons, a journey into Saxony, in order to discover the art of making tin plates; he fucceeded to his utmost wishes; and, on his return, feveral parcels of tin plates were made, which met with the approbation of the tin men in London and Worcester \*. Upon this fuccess, preparations were made for fetting up a manufactory, by the same persons who had expended their money in making the discovery; but'a patent being obtained by fome others, the delign was abandoned by the first projectors, and the patentees never made any plates; fo that the whole scheme seems to have been given up till the year 1720, when the fabricating of tin plates made one of the many very useful projects, (though they were mixed with fome which were impracticable) for which that year will ever be memorable. How foon after that year the manufacture of tin plates gained a lasting establishment, and where they were first made, are points on which I am not fufficiently informed; an old Cambridge workman has told me, that he used them at Lynn in Norfolk in the year. 1730, and that they came from Pontypool. The tin men, at the first introduction of the English plates, were greatly delighted with them; they had a better colour, and were more pliable than the foreign ones, which were then, and still continue to be hammered; it being impossible to hammer either iron, or copper, to so uniform a thickness, as these metals are reduced to by being rolled. It is faid, that a Cornist tin man flying out of England for a murder in 1243, discovered tin in Saxony, and that before that discovery,

des Police | James 178 .

<sup>\*</sup> England's Improvement by Sea and Land, by And. Yar-ranton, Gent. 1698.

there was no tin in Europe, except in England ; a Romish priest, converted to be a Lutheran, carried the art of making tin plates from Bohemia into Saxony about the year 1620+; and Andrew Yarranton, as we have feen, brought it from Saxony into England about the year 1670; Saxony at that time being the only place in which the plates were made. They are now made not only in England, but in France, Holland, Sweden, &c. though from the cheapness of our tin, and the excellency of some forts of our iron, the greatest share of the tin plate trade must ever center with ourselves. Our coal is another circumstance, which tends to give Great Britain an advantage, over fome other countries, in fuch manufactures as require a great confumption of fuel. Wood was scarce in Saxony above a century ago, and it is now still more scarce in France. They are beginning, it is faid, in that country to use coal and coak, or charred pitcoal, called by them Charbon de terre èpuré, and they have granted a patent to an individual for the preparation of it t. Another individual has begun to distil tar from pit-coal, and he gets about 5 pounds weight of tar from an hundred of coal (which is pretty nearly what I fuggested in 1781, as possible to be obtained from the same quantity, Vol. I. p. 267). The French § expect great advantage from this mode of depurating coal,

Heylin's Geog. † Yarranton.

Acad. des Scien. a Paris, 1781; where M. Lavoisier gives an useful memoir on the comparative excellencies of pit-coal, coak, wood and charcoal as fuels.—Il suit de ces experiences, que pour produire des essets égaux, il saut employer: charbon de terre 600 livres; charbon de terre charbonné 552; charbon de bois mêlé 960; bois de hêtre 1125; bois de chêne 1089.

6 Il suffit de dire qu'elle peut sournir à la capitale un nouveau chaussage, devenu necessaire dans un moment ou l'on est menace d'une dissette de bois; qu'elle peut ouvrit dans le royaume une nouvelle brance de commerce; etablir de nouvelles manusactures; faire valoir des mines, restees jusqu'a present inutiles. des Journ. Juillet, 1785.

but we have nothing to apprehend on that score, for the patriotic zeal of the Earl of Dundonald has put us in possession of every advantage which can be expected from a discovery, which he has had the honour of bringing to perfection.

The plating of copper is performed in the following manner. Upon fmall ingots of copper they bind plates of filver with iron wire, generally allowing 1 ounce of filver to 12 ounces of copper. The furface of the plate of filver is not quite fo large as that of the copper ingot; upon the edges of the copper, which are not covered by the filver, they put a little borax; and exposing the whole to a strong heat, the borax melts, and in melting contributes to melt that part of the filver to which it is contiguous, and to attach it in that melted state to the copper. The ingot, with its filver plate, is then rolled under steel rollers. moved by a water wheel, till it is of a certain thickness; it is afterwards further rolled by hand rollers, to a greater or less extent, according to the use for which it is intended: the thinnest is applied to the lining of drinking horns. One ounce of filver is often rolled out into a furface of about 3 square feet, and its thickness is about the three thousandth part of an inch; and hence we need not wonder at the filver being foon worn off from the sharp angles of plated copper, when it is rolled to fo great an extent. Plated copper has, of late years, become very fashionable for the mouldings of coaches, and for the buckles, rings, &c. of horse harness. It might be used very advantageously in kitchen utenfils, by those who dislike the use of tinned copper, and cannot afford to be at the expence of filver faucepans, &c. The filver, instead of being rolled on the copper to fo great a thinness, as it is in most works, might be left in kitchen furniture considerably thicker, so that an ounce of filver might be spread over one square foot; the filver coating would in this case still be very thin, yet it would last a long time. Fire does not confume filver, and

2634

the waste in thickness, which a piece of plate sustains from being in constant use for a century, is not much; as may be collected from comparing the present weight of any piece of college plate, which has been daily used, with

the weight it had an hundred years ago.

I do not know whether any attempt has ever been made to plate copper with tin instead of silver; I am aware of some difficulty, which might attend the operation, but yet it might, I think, be performed; and if it could, we might then have copper vessels covered with a coat of tin of any required thickness, which is the great desideratum in the present mode of tinning: but it ought to be remarked, that the thicker the coat of tin, the more liable it would be to be melted off the copper by strong sires.

The art of plating copper has not been long practifed in England; nor do I know whether it was practifed at an earlier period in any other country; for the Roman method of filvering copper was different, I think, from that now in use. Thomas Bolsover, of Sheffield, in the year 1742, was the first person in England who plated copper; it was applied by him to the purposes only of making buttons and snuss-boxes: soon after it was used for various other works; a person of the name of Hoyland, at Sheffield was the first who made a plated candlestick.

What is commonly called French plate, is not to be confounded with the plated copper of which we have been fpeaking; for though both these substances consist of copper covered with a thin coat of real silver, yet they are not made in the same way. In making French plate, copper, or more commonly brass, is heated to a certain degree, and filver leaf is applied upon the heated metal, to which it adheres by being rubbed with a proper burnisher. It is evident, that the durability of the plating, must depend on the number of leaves which are applied on the same quantity of surface. For ornaments which are not much used, ten leaves may be sufficient; but an hundred will

not last long, without betraying the metal they are designed to cover, if they be exposed to much handling or frequently washed. After the same manner may gold leaf be fixed, either on iron or copper. Gold is applied on filver, by coating a filver rod with gold leaf; and the rod being afterwards drawn into wire, the gold adheres to it; the finallest proportion of gold, allowed by act of parliament, is 100 grains to 5760 grains of filver; and the best doublegilt wire is faid to have about 20 grains more of gold to the fame quantity of filver \* It has been calculated, that when common gilt wire is flatted, one grain of gold is stretched on the flatted wire to the length of above 401 feet, to a furface of above 100 square inches, and to the thinness of the 492090th part of an inch; and M. de Reaumur fays, that a grain of gold may be extended to 2000 feet, and cover a furface of more than 1400 fquare inches; and that the thickness of the gold, in the thinnest parts of some gilt wire, did not exceed the fourteen millionth part of an inch +. The gold when thus applied, is thinner than when filver is gilt in the following manner, which is yet reckoned one of the cheapest ways, and is used in making various toys. Gold is disfolved in aqua regia; and linen rags being dipped into the folution, they take up fome particles of gold; the rags being burned to ashes, and the ashes being rubbed on the silver, the gold adheres to it, and is rendered visible by being well burnished.

## ESSAY XXXIV.

Of gilding in Or Moulu.—Of the Use of Quicksilver in extracting Gold and Silver from Earths.—Of Boerhaave's Experiments on Quicksilver.—Of silvering Looking-Glasses, and of the Time when that Art was discovered.

I HERE is another method of applying gold on copper or filver, which is much practifed; it is called gilding in Or Moulu. Quickfilver dissolves gold with great facility : if you spread a gold leaf, (not what is called Dutch leaf, which is made of brafs) on the palm of your hand, and pour a little quickfilver upon it, you will see the quickfilver absorbing the gold, just as water absorbs into its substance a piece of falt or fugar. Persons who have taken mercurial preparations internally, feldom fail to observe the readiness with which the mercury transudes through their pores, attaching itself to the gold of their watches, rings, sleevebuttons, or ear-rings, and rendering them of a white colour. A piece of gold, of the thickness even of a Guinea, being rubbed with quickfilver, is foon penetrated by it, and thereby made so fragile, that it may be broken between the fingers with ease: and if more quickfilver be added, the mixture will become a kind of paste, of different degrees of confistence, according to the quantity of quickfilver which is used. A piece of this paste is spread, by ways well known to the artists, upon the surface of the copper which is to be gilded in Or Moulu, and the metal is then exposed to a proper degree of heat: quickfilver may be evaporated in a far less degree of heat, than what is required to melt either gold or copper; when therefore the mixture of gold and quickfilver is exposed to the action of fire, the quickfilver is driven off in vapour; and the

the gold, not being susceptible of evaporation, remains attached to the surface of the copper, and undergoing the operations of burnishing, &c. too minute to be described, becomes gilt. This method of gilding copper, by means of quicksilver and gold, was known to the Romans \*Quicksilver will not unite with iron, yet by an easy operation, the foundation of which has been mentioned (Vol. I. Est. VI.), iron may be gilded in the same way, that copper or silver may. The iron is first to be made bright, and then immersed in a solution of blue vitriol, its surface will thereby become covered with a thin coat of copper, and it will then admit the gilding as if its whole substance was

copper.

It is this property which quickfilver has of uniting itfelf with gold, and it does the same with silver, which has rendered it of fuch great use to the Spaniards in America. They reduce the earths or stones, containing gold or filver in their metallic states, into a very fine powder; they mix this powder with quickfilver; and the quickfilver having the quality of uniting itself with every particle of these precious metals, but being incapable of contracting any union with any particle of earth, extracts these metals from the largest portions of earth. The quickfilver which has absorbed either gold, or filver, or a mixture of both, is separated from the fubstance it has absorbed by evaporation; the quickfilver flies off in vapour, and the fubstance remains in the vessel used in the operation. We have no mines of mercury in England; Sir John Pettus, indeed, fays, that a little cinnabar is now and then met with in our copper mines; and Mr. Pennant observes, that quicksilver has been found in its native state on the mountains of Scotland; and I have been

<sup>\*</sup> Æs inaurari argento vivo, aut certe hydrargyro, legitimum erat. Plin. Hist. Nat. L. XXXIII. Pliny understood by argentum vivum, native quickfilver, which is found in a fluid state in many mines; and by bydrargyrum, he understood quickfilver separated from its ore by sire; they are the same substance.

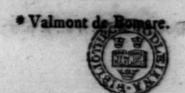

been shewn a piece of clay, faid to have been dug near Berwick, in which there were fome mercurial globules; but there are no works at prefent; where mercury is procured in any part of Great Britain: nor are there many mines of mercury in any part of the world. In the Philosophical Transactions for 1665, we have an account of the quickfilver mines of Idria, a town fituated in the country anciently called Forum Julii, now Padria de Fri-ouli, subject to the regency, and included in the circle of the lower Austria in Germany. These mines have been constantly wrought for above 280 years, and are thought, one year with another, to yield above 100 tons of quickfilver. In Hungary also, there are mines which yield quickfilver, but not so copiously now as formerly. Alonfo Barba mentions fome quickfilver mines in America near Potofi \* which, he fays, God Almighty provided to fupply the loss of this mineral, which is very confiderable in extracting the filver from the earths and flones with which it is mixed; but the mines of Almaden in Spain are the richeft, and probably have been wrought for the longest time of any in the world. Pliny speaks of the cinnabar which the Romans, with fomuch jealoufy, annually fetched from Spain, and 'tis very probable that they had it from Almaden, M. Jussieu informs us + that in 1717, there remained above 1200 tons of quickfilver in the magazines at Almaden, after a great deal had been fent to Seville in order to be exported to Peru, where the quickfilver, which is loft in extracting the filver, is faid to be at least equal in weight to the filver which is extracted. From 1574, when they began to register the quickfilver, which came to Potof upon the king of Spain's account, to the year 1640, there had been received, according to Alonfo Barba, 204600 quintals, belides a valt quantity irregularly brought of the transmittant of the patential

coming come quickling a may be tound \* Treatise on Metals, &c. by Alonso Barba, Eng. Trans. + Hift. de l'Acad. des Scien. 1719

in upon other accounts. This application of quick-filver to the extraction of gold and filver from the earths in which they are found, has rendered the confumption of it far more confiderable fince the discovery of the American mines, than it was amongst the ancients. Hoffman forms a calculation, and concludes, that fifty times as much gold as quickfilver was annually extracted from the bowels of the earth: Cramer admits admits the truth of this calculation, but influences a suspicion worth attending tothat mercury may often exist in minerals, and yet not be discovered by minets; since in the open fires in which minerals, whose properties are not known, are usually examined, the mercury would fly off in fume. Earths or minerals of any kind, containing mercury, are most accurately affayed by distilling them with iron filings; but whether a mineral contains mercury or not, may be easily discovered, by strewing it, when powdered, on a plate of hot iron, or on a hot brick covered with iron filings, and inverting over it a glass of any kind; the mercury, if the mineral contains any, will afcend and attach itself in finall globules to the fide of the glass. Mercury is divided by the writers of fystems of mineralogy, into native mescury, and mercury mineralifed by fulphur : native mercury is found in its running state, and quite pure, as it is faid (though this may be doubted from the facility with which mercury disfolves gold, and filver, and other metals) in the mines of Idria Almaden, &c. : it is more frequently, however, imbedded in calcareous earths, or clays of different colours, from which it may be separated either by trituration and lotion, the smaller globules coalescing by mutual contact into larger; or by distillation. The running native mercury, which requires no process for its extraction, is more esteemed, and thought to have some peculiar properties which do not belong to that obtained by fimple diftillation, though they both come under the denomination of

<sup>\*</sup> Ars. Docim. Cram. Vol. I. p. 231.

virgin mercury. Mercury mineralised by fulphur, is called cinnaber, which some fay is an African word denoting the blood of a dragon . Cinnabar is the most common ore of mercury, it is found in an earthy form refembling red ochre, fometimes in an indurated state, and though generally red, it hath been observed of a yellowish or blackish cast; it is mostly opake, but some pieces are as transparent as a ruby. This ore confifts of mercury and fulphur combined together in different proportions; some cinnabars yielding as far as 7, other not 2 parts in 8 of their weight of mercury. Sulphur and mercury, being both volatile in a small degree of heat, would rife together in distillation, unless some substance, such as quicklime or iron filings, was added to the cinnabar, which, by its superior affinity, unites itself with and detains the fulphur; whilft the mercury, not being able to support the heat, is elevated in vapour, and condensed in various ways in different works. It fometimes happens, that the coarfer cinnabarine ores are so much mixed with calcareous earth, that they require no addition in order to effect the separation of mercury from sulphur; this is the case in the mines of Almaden. The finer kinds of cinnabar, bearing a much higher price than mercury itself, are never wrought for mercury, but either used in medicine, or when levigated under the name of vermillion in painting; and often by the women as a substitute for carmine, which is prepared from cochineal. Native cinnabars are often mixed with finall portions of arfenical, vitriolic, or earthy fubstances, whence they become of uncertain or dangerous efficacy in medicine; for this reason Geoffroy recommends the use of factitious cinnabar, and the native, though formerly in great repute, has been left out of modern dispensatories. The finest cinnabar we know of is brought from Japan; though there is great reason to believe, that the Dutch impose upon the the world a home manufacture under the name of Japan cinnabar; the trade for gold, copper,

and cinnabar to Japan is exceeding lucrative, and I believe

wholly as to Europe in the hands of the Dutch. birth as to Thole, who are acquainted with the difficulty of making chemical experiments, will admire the great patience and industry with which Boerhause investigated the nature of mercury. He was induced to undertake this talk, from a defire of verifying, or refuting the doctrines of the alchemists. These adepts had taught, that mercury was the matter of which all metals confifted; and that if it could be cleanfed from fome original impurities, with which, even in its virgin state, they held it to be polluted, it would then become fit nutriment for the feed of every metallic fubstance: for, according to them, every metal forung from its peculiar feed, which, when it met with its proper pabulum, in a proper matrin, attended with a due follering heat, by a vivifying principle multiplied itself, and received an augmentation of parts, in a manner similar to that by which plants and animals are dilated in their dimensions. The investigation of nature is infinite, every age adds fomewhat to the common flock, which renders the labours of preceding ages wholly useless. We no longer trouble ourselves with the works of the alchemists which remain, nor do we regret fuch of them, as have been devoured by time, or were burned by the order of Diocletian; nay, even the Herculean labours of Boerhaave are become less interesting to us, and probably never would have been undertaken by him, had he been aware, that mercury would, in a proper degree of cold, become, like other metals, folid and malleable. In the Transactions of our Royal Society for the year 1733, we meet with Boerhaave's first dissertation upon mercury: his first experiments respect the change which the purest mercury undergoes from continual agitation; he included two ounces, which had been distilled above 60 times, in a clean bottle, and fastening the bottle to the hammer of a fulling mill which was almost constantly going, found in about eight months time above one eighth of the fluid, fpleadid, Vos. II.

\* Non-Common Persons, Vote Sand Str.

fplendid, infipid mercury, changed into a black powder, of an acrid braffy tafte. He next digested morcury in a gentle hear (180% of Fahrenheit's ther.) and found to, in a few months, changed into a powder, fimilar to what had been produced by agitation: both thelepowders, in a greater degree of fical were revivilied, or became sunning imercury again. He then enquired into the change which repeated diffillation could produce; after each operation he found a sed serid powder was as copionily separated, after the inbroury had been above 500 times diffilled; as at first; and thence reafoundly concludes, that it ought rather to be attributed to a change of the thercury itself, than to any impurity contained in it. This powder, like the preceding, by a faperior degree of hear became running mercury; except about a 72d part, which, though fixed in a strong fire and vitrifiable with borex, could not support the action of lead, but vamilhed entirely, leaving no ligns of any metallic fabiliance upon the empel: this thews the little probability of converting mercury into gold or fliver by the action of a violent fire. In the following year he presented a memoir to the Royal Academy of Sciences at Puris, upon the same subject. We there learn, that mercury kept in digertion for 15 years with a constant heat of 100 degrees, was not fixed, nor any how changed, except that a little black powder (which by imple grinding in a mortal became running mercury) was found flouring apon its furface. Hence is inferred, the impollibility of mercury's being changed in the bowels of the earth into any other metal, the heat in mines fearcely ever amounting to 1000. Though it might be impossible to change mercury into a metal, yet the philosophers by his contended, that mercury, united to a particular kind of sulphur, entered into the composition of all metals, and might by art be extracted from them; lead was of all others thought the most likely, and the experiment had been reported succeeded by Van Helmont, and others; but Boer have is positive, that nothing

nothing can be expected from its combination with faits, and lead, or tin. It was still thought by the alchemists, that mercury could never be freed from its original impurity, but by being joined to some pure body of the same nature with itself, this they thought gold and filver to be. Boerhauve, in order fully to fubvert their high pretentious, gave into the Royal Society another paper in the latter end of the year 1736, containing an account of the unchangeableness both of mercury and gold, how often foever they were diftilled together. He repeated the distillation of mercury from gold above 850 times; the mercury was not in any respect changed; its specific gravity was the same as at first, nor had it loft the property of being converted into a red powder by a due degree of heat. These were all the tracts. which were published during the life-time of Boerhaave; he died in September, 1738, and left his papers to his two brothers, and after their deaths, they fell into the hands of Charles Frederic Krusc, physician to the Empress of Russia; this gentleman hath published a short extract from Boerhaave's Diary, and promifes a fuller account of still more laborious operations. We learn from this extract, , that Boerhaave had distilled the same mercury roog times, and its specific gravity was to that of water, as 13 700: 1; whilft that which had been but once distilled was as 13 100: 1; a difference which may eafily be attributed to the different temperatures of the air when the experiments were made, or to other accidental circumstances, which the accuracy of Gravefande, with whom he made the experiment, could not provide against.

The mixture of quickfilver with gold, or filver, or lead or tio, or copper, or any other metallic fubstance with which it is capable of uniting, is called an amalgam, and the operation by which the union is effected, is called amalgamation. Authors are not agreed as to the derivation of the word amalgam, some think that it is composed of two Greek

cille ni basa Alekari

Novi Commen. Petropo. Tom. IX. p. 381.

words (was and yapan) by which the intimate union, or marriage, as it were, of the two metals is denoted; others are of opinion, that it ought to be written a malagma, and that it is derived from a Greek word (paragon) fignifying to fosten, inasmuch as the metal, be it what it may, is always softened by its union with the mercury. An amalgam, made of four parts of tin and one of quickfilver, in the form of a ball, is used by some under the pretence of purifying water; it cannot, I think, contribute in any manner to that end; but as the ball is always boiled in the water, the seeds of vegetables, or the fish spawn, or the animalcules, &c. with which water is often polluted, may be precipitated by the action of boiling. But there is another purpose to which a mixture of tin and quickfilver is applied with great utility—the silvering of looking-glasses.

Tin may be beat out into leaves not thicker than paper, called foils; on tin foil, fitly disposed on a flat table, quick-filver is poured, and gently rubbed with an hare's foot, it soon unites itself with the tin, which then becomes very splendid, or, as the workmen say, is quickened: a plate of glass is then cautiously slid upon the tin leaf, in such a manner as to sweep off the redundant quickfilver, which is not incorporated with the tin: leaden weights are then placed on the glass, and in a little time the quickfilvered tin-foil adheres so firmly to the glass, that the weights may be removed without my danger of its falling off. The glass thus silvered is a common looking glass. About two ounces of quickfilver are sufficient for covering three square

feet of glass.

It is generally believed, that the art of making looking glasses, by applying to their back surface a metallic covering, is a very modern invention. Muratori expressly says, that glass specula, such he means as are now in use, are not of any great antiquity.—Serie autem antiquitati novimus suisse specula, quorum usus nunquam desit; sed corum fabricam apud Italot unice forsan Veneti per tempora multa servarunt et adhuc servant: que tamen alio translata nunc in aliis quoque

quoque regnis floret .- The authors of the French Encyclopedie + have adopted the same opinion, and quoted a Memoir printed in the 23d vol. of the Academy of Inscriptions, &c .- Il est d'autant plus étonnant que les anciens n' aient pas conqu l'art de rendre le verre propre à conservir la représentation des objets, en appliquant l'etain derriere les glaces, que les progrés de la découverte du verre furent, chez eux, pousses fort loin .- Mr Nixon, in speaking of the glass specula of the ancients, says, " before the application of quickfilver in the construction of these glasses (which I prefume is of no great antiquity) the reflection of images by fuch specula, must have been effected by their being besmeared behind, or tinged through with some dark colour, especially black t." I have bestowed more time in searching out the age in which the applying a metallic covering to one fide of a looking-glass was introduced, than the subject in the estimation of many, will seem to deserve; and, indeed, more than it deserved in my own estimation; but the difficiles nuge, the stultus labor ineptiarum, when once the mind gets intangled with them, cannot be eafily abandoned: one feels, moreover, a fingular reluctance in giving up an unfuccessful pursuit. The reader would pardon the introduction of this reflection, if he knew how many musty volumes I turned over before I could meet with any information which could fatisfy me, in any degree, on this fubject; I am not yet quite satisfied, though I take the liberty to fay, in opposition to Muratori, and the other respectable authorities which I have quoted, that the applying a metalng to looking-glaffes is not a modern invention; it is probable it was known in the first century, if not sooner, and it is certain, I apprehend, that it was known in the fe-

The Romans, before the time of the younger Pliny, not only used glass, instead of gold and filver, for drinking ves-

his, but hey knew how to glaze their windows with it, and they fixed it in the walls of their rooms to render their in the fide of a room, is a fore of looking-glass, and if the fuces into which it is fixed, be of a dark colour, it will not be a very bad one. And hence I think the Romans could not fail of having a fort of glafs specula in use: but this, though admitted, does not come up to the point; the ques-tion is, Whather they covered the posterior surface of the glass with a metallic plate? It has been observed before, that the Romans knew how to make a paste of gold and quicksilver, and it appears from Pliny also, that they knew how to best gold into this leaves, and to apply it in that state both on wood and metal: now there is a passage in Pliny, from whence it may be collected, that the Romans began in his time to apply a coat of metal to glafs specula, and that this coat was of gold. The passage occurs in the very place where Pliny professes to finish all he had to observe concerning specule. An opinion, says he, has lately been entertained, that the application of gold to the backpart of a speculum, readers the image better defined. It is hardly possible that any one should be of opinion, that a place of gold put behind a metallic speculum, could have any effect in improving the restocked image; but supposing Pliny (whole transitions in writing are often abrupt) to have passed from the mention of metallic, to that of gloss speculo, then the propriety of the observation relative to the improved state of the image is very obvious. If we suppose the Romans in Pliny's age to have simply applied some black substance to the back surface of the place. Pliny, from whence it may be collected, that the Romans ans in Pliny's age to have simply applied some black ance to the back surface of the glass, or even to have known how to put tin behind it, yet the observation of the The Romans Protoco the time of the country White said

Atque ut omnio de speculis peragantur hoc loco. Optima apud majores suerant Brundusina sanno et zre mixta. Prelata sunt argentes Primus secit Praxiteles, magni Pompeii zetate. Nuper cress expenso certiorem imagiaem reddi auro apposito aversis. Hist. Nat. L. XXXIII. S. XLV.

image being rendered more distinct by means of gold, might have been made with more justice than is generally supposed; for Buffon is of opinion, that a looking-glass made with a covering of gold and quickfilver, would reflect more light than one made in the ordinary way with tin and quickfilver\*; and hence Pliny's expression, certiorem imaginem reddi auro apposito aversis, will be accurately true.

Alexander Approdifeus flourished towards the end of the fecond century, he wrote several works in Greek, and amongst the rest, two books of Problems, one of his problems is this +:

Why are glass specula so very resplendent ?

The only part of the answer which we are concerned with, is,

Or credit and xenone recommend and or or or or or

Because they befmear the infide of them with tin-

The Greek word which I have here rendered before, does not clearly point out the manner in which the operation of fixing the tin upon the glass was performed. Pliny uses a Latin word (illitum) of exactly the same import as this Greek one, when he speaks of copper vessels being tinned; and as in that operation, tin is melted and spread over the furface of the copper, I see no difficulty in supposing, that the tin may have been, in the time of Alexander Aphrodiseus, melted and spread over the surface of the glass, when previously heated.

Having carried up the invention of covering glass specula with a metallic coating of the second century, we may be the

\*Ou pourroit trouver le moyen de faire unmeilleur étamage, et je crois qu' on parviendroit en employant de l' or et du vifargent. Hist. Nat. Buffon. Sup. Tom I. p 451.

† ΑΛΕΞΑΝΔΡΟΥ ΑΦΡΟΔΙΣΕΩΕ ιστεμες σετομισία και φυσικα σεοδληματα. Parifiis, 1541.—If there be any doubt concerning the authenticity of these problems, I leave it to be discussed by the Critics.

the more ready to admit that the Sydonians possessed this art, before Pliny wrote his Natural History: for in that work, he not only praises them for their former ingenuity in various glass manufactures, but he adds - and they had invented specula also . - Now there is some reason to think, that if the Sydonians had only invented the art of using a flat piece of glass as a speculum, without knowing how to give it a metallic coating, on which its excellency chiefly depends, they would not have merited the mention which Pliny makes of them; for their looking-glasses must have been inferior to the metallic mirrors then in use at Rome. There feems to be but one objection of any confequence to this conclusion, - had the method of giving a metallic covering to plates of glass been known, at least to the Romans, (for it might have been known in Afia long before it was known in Italy) it feems probable, that the metallic specula would have fallen into general difuse, much fooner than there is cause to think they did; for it would have been much easier to make a looking-glass, than to polish a metallic mirror; and the image from the glass would have been superior to that from the metal, and on both

accounts the mirrors would have become unfashionable.

The first mode of fixing a coat of tin on a looking-glass, I fulpect to have been that of pouring the melted metal on the glass; and I have some reason, not now to be insisted on, to think, that this mode was not disused in the fourteenth century, - Baptista Porta lived in the fifteenth, and died towards the beginning of the fixteenth century; he gives us a very accurate description t of the manner in which looking-glasses were then silvered; it differs from that now in use only in this, that the tin-foil, when filvered, was taken up and gently drawn upon the glass. J. Mau-

o. I me Toud see Tom I. o.

Alind (vitrum) flatu figuratur, aliud torno teritur, aliud ar-genti modo calatur, Sydone quondam iis officinis nobili, fiquidem eriam specula excogitaverat. Hist. Nat. L. XXXVI.

vice Hoffman published his Alla Laboratorii Chemici in 1719; he there speaks of a mixture of 1 part of tin with 3 of quickfilver, which sometime ago, he says, was usually applied to the back furfaces of looking-glasses; although the Venetians did then make looking-glasses by pouring quickfilver upon tin-foil placed on the back furface of the glass. - This mode of filvering the glass was not then invented by the Venetians, as appears from what Baptifta Porta had advanced above two hundred years before; though the mode of filvering the tin-foil, when laid upon the glass, was an improvement on that prescribed by Baptista Porta, just as the mode now in use, is a great improvement on that practifed by the Venetians in the time of Hoffman.

The men who are employed in filvering looking-glaffes often become paralytic, as is the case also with those who work in quickfilver mines; this is not to be wondered at, if we may credit Mr. Boyle, who affures us, that mercury has been feveral times found in the heads of artificers exploed to its fumes . In the Philophical Transactions +, there is an account of a man, who having ceased working in quickfilver for fix months, had his body still so impregnated with it, that by putting a piece of copper into his mouth, or rubbing it with his hands, it instantly acquired a filver colour. This, though a furprifing, is not a fact of a fingular nature; it is well known, that fulphur, taken inwardly, will blacken filver which is carried in the pocket; and I have somewhere read of a man whose keys were rusted in his pocket, from his having taken, for a long time, large quantities of diluted acid of vitriol. I remember having feen at Birmingham, a very flout man rendered paralytic in the space of fix months, by being employed in fixing an amalgam of gold and quickfilver on copper; he stood before

the month of a finall oven strongly heated, the mercury was converted into vapour, and that vapour was inhaled by him. A kind of chimney, I believe, has of late been opened at the farther side of the oven, into which the mercurial vapour is driven, and thus both the mercury is saved, and the health of the operator is attended to. The person I saw was very sensible of the cause of his disorder, but had not courage to withstand the temptation of high wages, which enabled him to continue in a state of intoxication for three days in the week, instead of, what is the usual practice, two.

Of the transmutability of Water into Earth.

The same and a local and the same and the sa

the mean are the feether. Books as no affines parties pricedly SIR Ifaac Newton and Dr. Bently met accidentally in London; and on Sir Ilaac's inquiring what philosophical oursuits were carrying on at Cambridge, the Doctor replied None-for when you go a hunting. Sir Heac, you kill all the game: you have left us nothing to purfue; Not 10, faid the philosopher, you may start a variety of a ne in eve ry hush, if you will but take the trouble to best for it. And so in truth it is a every object in a ent, and every ex phical experim de, even with an exp restigation, incidentally suggests make restigation, incidentally suggests make not as in contemplating the civil history of the under the necessity of being contented with remembering the great with remembering the great state. investigation, incidentally for of its feveral parts, with remembering the great revolutions of its feveral parts, with remembering the great revolutions which have in fact taken place; without minutely exploring all the fecret causes, all the fortuitous circumstances by which they were effected; so in the present state of capariments which they were effected; so in the present state of capariments.

jects, with knowing the general conclusions, without attempting to scrutinize all the particular experiments, on which they are founded. All the works of the writers of Greece and Rame, which have come down to our time, do not equal a third part of the bulk of those which have been published by individuals, and by the feveral philosophical focieties of Europe on experimental philosophy alone, fince the middle of the last century: nor does the nature of things prescribe any limit to human industry, exerted in the profecution of fuch inquiries. There is not an animal, or a vegetable substance that we feed on; nor a saline substance that we take; nor a beverage that we drink; nor the air that we breathe; nor a metal that we handle; nor a stone that we tread on, but what may furnish matter for an infinity of experiments. What a fource of natural knowledge is water alone? Who can understand all the properties that belong to it as a body, that is fluid in a certain degree of heat; folid in a lefa; and convertible into an elaftic vapour of incredible force in a greater; as capable of diffelving all kinds of falts; as abforbing and detaining in its fubflunce the air of the atmosphere; as being itself abforb-ed by, and suspended in the air; as constituting the principal part not only of blood, urine, milk, wines, oils, fpirits, and all fluid bodies; but as entering, in a large proportion, into the confliction of the folid parts of all animal, and vegetable, and of many mineral fubfiances; as being refoliously, according to the most recent discoveries, into two different forts of air; and as being transmutable into earth it It is concurning the experiments which have been made re-lative to this last property, that I mean, in this Essay, to give a brief historical account. Men advance very flowly in the attainment of physical knowledge; the trouble of making constituents it grass, but those relations of their refults cannot fail of being contraining to minds imbued with any talks for fuch hind of investigations and there are few questions of greater importance in the aftiguation of speculative phis september 100 Bell there

losophers, than that which respects the transmutability of water into earth. If but one particle of water can by any means be changed into a particle of earth, the whole doctrine of the *Peripatetic* sect, concerning the *Elements* of things, will be utterly subverted; the diversities of the bodies substituting in the universe, will no longer be attributed to the different combinations of earth, air, fire, and water, as distinct, uncompounded, immutable principles; but to the different magnitudes, figures, and arrangements of particles of matter of the same kind.

Those who maintain the transmutability of water into earth, support their opinion, principally, by arguments deduced from the result of two very different kinds of experiments. In the one they appeal to the mechanism of nature, and contend, that vegetation, however inexplicable it may be in its manner of operation, is certain in its effect, and invariably changes water into earth. In the, other they have recourse to the assistance of art, and by so simple a process as that of distillation, indefinitely repeated, they hold it possible to exhibit any determinate quantity of water under the form of a white, impalpable, opske, insipid powder.

When the vall genius of Bacon had rendered the authority of Arifatle less respectable, and men's minds were every where alarmed with a suspicion, that Truth and He might possibly be on different sides; several appearances in nature, which had either escaped the observation, or, from seeming repugnant to the established maxims of the Schools, had been deemed unworthy the animadversion of philosophers, began to be examined with a minute attention; we have an instance of the truth of this observation in the subject before us.

The puteft water could never have been wholly distilled in glass vessels, but the operator might have had an opportunity of observing a thin pellicle of earth, tarnishing the transparency, and adhering to the bottom of the vessel employed

employed in the process. This appearance is constant, it prefents itself not only when the water is first distilled, but after it has been purged, as much as possible, from every foreign impurity by reiterated distillation. Yet notwithstanding the invariable uniformity of this phenomenon, I know not whether it was noticed by any one before Borrichius, as furnishing an incontrovertible proof of the transmutability of water into earth. Why, fays he, should we dwell upon the possibility of chemical principles being converted into one another, when the very elements of Aristotle are not exempt from change? He then proceeds to observe, that water, how frequently soever he had distilled it from fresh glass vessels, still left at the end of each fuccessive operation, a slender coating of earth sticking to the fide of the veffel, and he attributes the production of this earth, not to any extraneous impurity accidentally mixed with, and obstinately adhering to the water, but to a transmutation of the water into a true, firm, fixed, insipid earth". In faying that Borrichius was the first person who made this observation, I may, perhaps, be guilty of some innaccuracy. The imprimatur for Borrichius book, here referred to, is dated at Copenhagen in 1673; now it is certain, that Boyle's treatife concerning the origin of Qualities and Forms, in which the transmutation of water into earth by distillation, is distinctly mentioned, was published at t confirmed him is bisconjecture, that the

DEPT. H. D. CIG.

Et quid chemica moramur? Ipsa Aristotelis elementa non funt ab hie immunia mutationibus. Oxford in 1666; yet as Borrichius had spoken of this experiment to a physician at Oxford ten years before he published his book, and as it is very probable, that Boyle was unacquainted with this experiment when he first published his Sceptical Chemist in 1661, Borrichius may, perhaps, be properly enough esteemed prior to Boyle in the invention and application, though posterior to him in the

twell upon the politicist

publication of the experiment.

Boyle, however, examined the matter with greater precision than Borrichius had done. In his treatise concerning the origin of Qualities and Forms, he acquaints us with the first occasion of his making the experiment \* A gentleman who, in order to discover the grand arcanum, had employed, among other things, great quantities of purified rain water, complained to him, that inflead of obtaining what he looked for, he met with a great deal of whitish excrementitious matter, which he knew not what to make of. The great plenty and fome peculiar qualities of this matter, which had so much perplexed the old chemist, fuggefted to Mr. Boyle a fuspicion, that it was not owing to any accidental foulness of the water, and put him upon trying, whether water, which had been previously purified by distillation, would not, by being re-distilled, leave, at the end of the operation, a portion of earth. The refult of his experiment confirmed him in his conjecture, that the earthy powder obtained by distilling rain water, might be a transmutation of some parts of the water into earth : and he was much ffrengthened in this belief by converting with a phylician (probably the fame person mentioned by Borrichius) who affured him, that he had frequently found a white earth in distilled rain water, even after he had distilled the fame numerical liquor a great many times.

Boyle seems to have been very cautions in admitting this transmutation, the oddness of it he owns still kept him in suspense; and it was not without much delight,

<sup>\*</sup> Boyle's Works, fol. Vol. II. p. 519.

that he was informed by an ingenious person of unsuspected credit, who, with a medical view, had been long working upon rain water, that water which he had distilled near two bundred times, full afforded a white earth ; and that more copiously, at least more conspicuously in the latter diffillations, than in the former. This gentleman, out of one onnce of distilled rain water, had obtained, by reiterated distillation, near three quarters of an ounce, if not more of earth. The physician Dickenson, mentioned by Borrichius, was probably the person alluded to by Boyle in this account; for Houghton lays in his Collection, it I have heard that Dr. Dickenson has turned eighteen parts of water out of twenty parts into earth, only by repeated distillation." Yet, even this account, conclusive as one might think it, could not extort from Boyle a full conviction of the possibility of transmuting water into earth by distillation; he calls the hypothesis a bold conjecture, and expressly mentions some scruples which still remained with him. Two of these scruples are worthy of particular notice, inafmuch as they contain the two principal objections, which have been made, by subsequent philosophers, to the doctrine which he endeavoured to establish. The first respects the welfels in which the experiment had been usually tried; the second has relation to the water itself. \_" It were fit to know," fays he, " whether the glass body, wherein all the distillations are made, do lose of its weight, any thing near fo much as the obtained powder amounts to."-And again, "I could wish that it were demonstrably determined, what is on all hands taken for granted, that distilled rain water is a perfectly homogeneous body the drup can return to mineral walk at the free w

It does not appear that Boyle was ever fully fatisfied with respect to these doubts, he resumes indeed the subject in a tract, intitled, Experiments and Notes about the produceableness of Chemical Principles, published at Oxford in the state of the s

1680, and mentions a new trial which he had made ; yet he there repeats his fcruple concerning the homogeneity of water, and though upon the whole he appears willing to believe, that water might be transmuted into earth by diffillation, and the nature of his subject led him to make the most of so remarkable an experiment, yet he candidly owns, that some of his experiments afforded strong probabilities.

bilities, rather than conclusive proofs.

Notwithstanding the diffidence with which Boyle himfelf proposed his opinion concerning the transmutability of water into earth, it appears to have been very generally admitted from his time to Beerbasee's; and even Newton? to far believed it, as to think it poslible that water might e made red hott noncon and pare to

Though

Baerbaave opposed the general persuasion, he did not deny that earth was always found at the bottom of the glass vessel in which water had been distilled, nor that the quantity of earth was constantly increasing with the increase of the number of distillations which the water had undergone; but he thought that this earth did not proceed from the water itself, but from the dust which is always floating in the atmosphere, especially in the atmosphere of elaboratories. It could not be imagined, that the atmosphere included in the vessels used for distillation, could furnish any considerable quantity of dust in one operation, yet being renewed by the opening of the vessels, as frequently as the distillation was repeated, it seemed to him to be a cause fully adequate to the effect.

It is a matter of wonder, that Boerhaave should assign such a reason for this phenomenon, considering the result of an experiment mentioned by Boyle, in which he exposed the same water, in the same vessel bermetically sealed, to a digostive heat for above a year +: after it had continued a good while, little concretions, heavier than the water, began to be formed, and he expressly remarks, that the longer the glass was kept in the digestive furnace, the more of this fine terrestrial substance was produced; an event impossible to be explained from the dust storing in the atmosphere, as the vessel, by being hermetically scaled, effectually excluded the minutest particle of dust from coming in contact with the water.

Vol. II. Mm

\* Boerh. Chem. Vol. L. p. 627.

† When the neck or hollow stem of a glass vessel is so softened by sire, that the two sides of it may be pinched together, the vessel is said to be bernetically sealed, thus the upper end of the tube of a mercurial thermometer, is hermetically sealed. — A digestive heat, is in general, any degree of heat above that in which water seasons, and below that in which it boils: but 150° of Farenheit's thermometer is commonly called a digestive heat. The operation called digestion, consists in exposing liquids, or liquids and solids, to a digestive heat in suitable vessels for a due time.

Though this experiment, properly confidered, was certainly conclusive against Boerhaave's hypothesis, yet Marggraf undertook to shew its insufficiency in another manner \*. He contrived a retort and a receiver of the same piece of glass, and through an hole in the receiver, which he afterwards closed with a glass stopple, he poured an ounce of water which had been carefully distilled thirteen times; this water he re-diffilled, without fuffering any air to enter into the retort, thirty times more, and observed that the water, which was at first exceedingly transparent, became more and more troubled by the admixture of a fine white earth, as the number of distillations was increased. The refutation of Boerhaave's hypothesis, was not the only point which Marggraf had in view in making his experiments on water; he was defirous also of obviating the objections of those who were disposed to attribute the origin of the earth to an abrasion of the parts of the glass, rather than to a transmutation of the particles of water. In order to this he has not only remarked, that the vessels in which he had dittilled water fo frequently, were, as far as microfcopes could inform him, as perfectly polished as when new, and that they were of the very best fort of glafs, in which fpirit of falt might be kept for many years without its injuring them, but he has shewn that fire is not essential to the production of the effect; an earth being separable from distilled water by the simple action of the sun evaporating the water, and even without any heat by a long continued agitation. Sir Isaac Newton was of opinion, that the water upon the furface of the earth was daily diminished by vegetation, and if we may rely upon these experiments of Marggraf, we fee that there are two other causes which have a tendency to produce the same effect; for the water of the ocean is incessantly raised into the atmosphere by evaporation, and agitated by the action of the winds and a tradition of the second relief the alleged to a second to a stides;

marchip difficial a dietare healt. The operation

Opuf. Chy. de M. Marggraf, Vol. II. p. 176.

tides; and if it be by both these causes converted in part into earth, we may admit that the Caspian sea is less now than it was formerly, and that the Mediterranean sea has retired from the coasts of France, Spain, Portugal, and Italy, without having recourse, with Busson, to the sinking of immense caverns within the bowels of the earth, into which the sea has from time to time retired. With respect, however, to this supposed diminution of the sea, it may be observed, that it is well understood that the sea has encroached upon the shore in some places, and deserted it in other; but I do not know whether geographers are able, on solid grounds, to say,—whether the quantity of land throughout the whole globe, is, or is not, the same now that it was 4000 years ago.

M. Eller had, in 1746, obtained earth from water by triturating it in a glass mortar\*; and Wallerius, in 1760, with a view of removing the suspicions of Pott, who thought the earth proceeded from the mortar itself, varied in some measure Eller's experiment, by triturating water in mortars of iron and bronze†. The old proverb, — gutta cavet lapidem — would render experiments of this kind very suspicious, if the authors did not assure us, that the earths obtained by trituration, were not of the nature of the vessels in which the experiments were made: and Marggraf also affirms, that the earth which he procured from water by repeated distillation, had properties very different

from those of pounded glass.

In opposition to the opinion of these philosophers, M. Le Roi has undertaken to shew ‡, that the very experiments produced by Marggraf and others, in proof of the transmutability of water into earth, do not, though they be admitted in their full extent, sufficiently establish the fact.

- Calle is with the performance of the walls of the work of the walls of the walls

Mem. de l' Acad. de Berlin, 1746.

<sup>†</sup> Recueil des Mem. de Chy. Vol. II. p. 542.

Hift. de l' Acad. des Scien. a Par. 1767.

His reasoning turns chiefly upon the second of Boyle's feruples before mentioned : he apprehends that rain water ought not to be effeemed an homogeneous fluid, but that it contains an earth fubtilely mixed with, or diffolied in the water, from which it cannot be separated by any number of distillations, however great. - Marggraf himself was quite aware of this difficulty; he fays he fulpected, that water which had been distilled but once by the retort, might probably contain fome portion of attenuated earth which had rifen in the distillation, but which did not belong to the water; and he therefore distilled the water, on which he made his experiment, thirteen times, and fix of them with the gentle heat of boiling water. That rain water, collected with every possible precaution, contains not only a portion of earth, but small quantities also of the acids of nitre and fea falt, is proved beyond a doubt by the experiments of Margoraf himfelf; the only point in dispute is, whether these hererogeneous admixtures can be separated from water by renerated distillation or not? M. Le Roi thinks, that they cannot; according to him, the vapour of water, which rifes in distillation, carries with it a portion of the impurities contained in the water. This objection may recur for ever, let the number of distillations be what they may, nothing those of a complete transmutation of a definite quantity of water can wholly obviate it.

The experiment before mentioned, in which Boyle's friend obtained from an ounce of water, near three quarters of an ounce of earth by 200 diffillations, approaches the nearest of any that has ever been made to a complete transmutation; but this experiment has of late been considered by M. Le Roi and others, as muriting no manner of attention; principally because it does not correspond with similar experiments of more modern chemists, especially of Marggraf, whose accuracy is above all question. He could not obtain from 72 ounces of pure rain water, by 13 distillations, above 12 grains of earth; a quantity very inconside-

Table

rable, in comparison of what it ought to have been, in order to have agreed with the quantity obtained by Boyle's friend.

I have no intention to enter into a formal defence of this famous experiment mentioned by Boyle; it may be obferved, however, that neither Marggraf, nor any other chemist, ever distilled the same identical water so frequently, as the author of this experiment did : his relation of it then, it is evident, is not contradicted from obfervation, but from inference, and the inference has been founded on a principle, rather taken for granted, than proved. The principle is this,—that if any number of distillations, suppose ten, yield a certain portion of earth, twenty times that number, or 200 diffillations, would yield twenty times as much, at least not more, earth. Now there are some reasons to believe, that this princip is not true; for not to infift on what Boyle, however, intimates, of the earth being more plentifully afforded in the latter distillation, than in the former, Margarat himfelf has made two observations, which, when taken together, feem to prove the fame thing. He affirms, and Wallerius agrees with him, that more earth is separated when water is kept boiling with a frong than with a gentle heat; and he observes also, and esteems it a fact altogether fingular, that water which has been often distifled, requires for its elevation, especially towards the end of the operation, when but a fmall quantity remains in the retort, a degree of heat exceedingly strong, when compared with Mm3

the file of the cold design and the file of

This observation is not, I believe, true; Boerhaave is said to have distilled the same water 500 times; I have not seen all the works of Boerhaave, nor does the author, who makes this remark concerning him, refer to the particular part of his works where the fact is mentioned. Fourtroy's Chem, Eng. Trans. Vol. I. p. 115.

that which any other water requires \*. From these observations I would argue thus if it be true, that more earth is separated when water is distilled with a strong than with a gentle heat; and if it be true also, that the degree of heat necessary to distil water is stronger, as the number of distillations it has previously undergone is greater, will it not be a just consequence, that the quantity of earth separable by a fingle distillation, or by any definite number of distillations, will be greater as the number of previous distillations has been greater? if this be admitted, it eafily follows, that the quantity of earth separable by 200 distillations, cannot be properly calculated by the rule of proportion, from what actually has been separated by 13, or any other number of distillations fo greatly short of 200. Moreover, this experiment is not destitute of a kind of collateral proof; for Wallerius has observed, that the quantity of earth which he obtained by triturating a certain quantity of water in a glass morter for four days, agrees pretty exactly with the quantity procured by the 200 diffillations mentioned by Boyle.

M. Lawisser + rejects the notion of the transmutability of water into earth by distillation, as well as M. Le Roi; but he rejects it upon different principles: he has endeavoured to remove the other scruple mentioned by Boyle, and has done, what it is surprising no chemist ever thought of doing before his time, considering that the hint had been

+ Hift. de l' Acad. des Scien. a Paris, 1770.

pendant la distillation, il saur entretenir continuellement l'eau que la retorte contient, dans une forte coction. Ou trouvera que, par ce moyen, il se sépare toutes les sois plus de terre de l'eau, que quand la distillation se fait lentement.—Ou doit remarquer comme quelque chose de tout-a-sait particulier, que plus souvent une semblable eau est distillée, et plus l'operation devient disseile, sur-tout a la sin, quand une partie de la liqueur a distillé; car alors le residu demande un dégré de su tres-vébément en comparaison de toute autre eau. Opus, de Marg. Vol. II, p. 193.

been given above 100 years ago; he has weighed the glass vessel in which the operation was performed, and has found that its weight after the operation, is less than it was before the operation; and this loss of weight he attributes to the abrasion, or solution of the parts of the glass. M. Lavoisier's experiment resembles that of Boyle before mentioned, in which water was exposed to a digesting heat, in a vessel hermetically sealed; but he conducted it with more accuracy. I have three reasons for hesitating concerning Mr. Lavoisier's opinion, which refers the earth found in the veffel after the distillation of water, to the abrasion of the glass. In the first place, the earth procured by distillation, is not of the same kind, has not the same chemical properties, as pounded glass has. Secondly, Mr. Lavoisier did obtain a grains of earth, above the loss of weight which his veffel had fultained, and this quantity may, perhaps, be as much as ought to be expected from fuch an experiment, supposing that water is convertible into earth; for the heat he made use of in the operation was fmall. And laftly, I have flowly distilled water in a filver retort, and afterwards evaporated the distilled water on a polished silver plate, there remained on the plate a small pellicle of earth. When a drop of water, arifing from the vapour condensed in the top of a filver tea vale, happens to fall upon the body of the vafe, it is prefently evaporated; but it always tarnishes the spot on which it has fallen. I am aware it may be contended, that the earthy pellicle in both these cases, may be attributed to a precipitation of the dust floating in the atmosphere, or to an attenuated earth, which is mixed with the water and carried up by the vapour. On the whole, the possibility of converting water into earth by distillation, remains, I think, still an undecided problem; M. Lavoisier's experiment staggers the confidence I had reposed in the conclusions of Marggraf, but it must be repeated with success before it will utterly fubvert it.

do the both of water. .

With respect to the conversion of water into earth by vegetation, many philosophers of great eminence have admed it without fcruple. Van Helmont " derived not only vegetables but all fubstances whatever from water, and boulted that he was the first author of that hypothesis. It may be observed, however, that in the earliest systems of philosophy, we have the plainest allusions to this doctrine, and to the Mofaic account of the creation. Thus Berofus, the famous priest of Babylon held water and darkness; (deedness, was upon the face of the deep, Gen. i. 2.), the Phenicians darkness, a chaos, and wind; the Persians light, to have been the first principles from which all things proceeded. The most ancient Greeks, if the opinion of Homer be of any weight in this matter, derived the origin of all things from water; this doctrine was followed about 300 years afterwards by Thales of Miletus; who, travelling into Egypt and converting, as Diogenes Lacrtius tells us, with the priefts of that country, heard from them, probably, fome tradition concerning the creation; by which means he coved much upon the poet, teaching, as Cicero observes,

Van Helmont + produced a fingular experiment in support of his opinion, that water became earth by vegetation. He took an earthen vessel and put into it 200 pounds weight of earth, which had been previously dried in an oven; he wetted the earth with rain water, and planted in it the trunk of a willow which weighed sive pounds. In the space of sive years, the willow weighed 100 pounds 3 ounces: the earth was watered, when it was necessary during the whole of the time with either rain or distilled water; the vessel was spacious, and was funk into the ground, and, to prevent any dust from falling into it, its mouth was covered

+ Opera omn. p. 105.

De Lithiafi, C. I. S. IV.—Aft ad me usque nescitum suit, cunch corpora, que missa creduntur, materialiter duntavas exsola aqua esse, nullo excepto.

with tin plates, which were pierced with many holes. No account was taken of the leaves which fell in four fucceffive autumns. The earth was taken out of the veffel, dried. and weighed at the expiration of the five years, and it had lost only about 2 ounces, fo that 164 pounds of wood, of bark, and of roots, of which the tree confilted, had arifen from the water. I have related this experiment at full length, as it is the first of the kind which was made, and is as conclusive as any of those which have been made since by Boyle, Du Hamel, Eller, and others. Beccher admits the fact as stated by Van Helmont, but he objects to the conclusion; water, fays he, will never become earth, except fo far as it carries fome earthy particles along with it . M. Le Roi adopts the fame notion, when he attributes the increase in the weight of the willow, to the earthy and faline particles from which water cannot be freed, even by distillation. It is, moreover, well known, that plants fuck in nutriment from the air by their leaves, and this nutriment is not a pure water, fince the purelt atmospherical water contains both oily, faline, and earthy principles, if we may trust the analyses which have been made of it. In addition to this remark, I would observe, that though the willow gained an increase of 164 pounds in Maria Carrie and and the train to the

<sup>\*—</sup>nec fufficit folis verbis omnium rerum originem aqua tribuere, aut experimentum Helmontii in vegetatione arboris, quod

Beccher Phy. Sub. p. 87.—Calcined plasterstone, and the materials used in making earthen ware, absorb much water, and are
increased in weight, as vegetables are by absorbing water in vegetation; and some are of opinion, that water, by being united to
what is called (from the substance which yields it by a peculiar
process) sparry acid, may be changed into a slinty earth; but in
all these, and in other similar cases, it may be questioned, whether
the particles of water may not be wholly distunited from the substances with which they are combined, and again exhibited under the form of water.

weight, yet a very fmall portion of that weight was earth fince much the greatest part of all vegetables, and especially of fucculent ones, confishs of water and air. I cut a leaf from the mitre aloe, it weighed 1644 grains; it was cut into flices, and exposed to the heat of the atmosphere in September; in 15 days it had loft 1558 grains: I then burned it to a black ash, it weighed in that state 26 grains, and being burned to a white ash, it weighed only 16 grains, which were composed only in part of earth; for they contained, though I omitted to examine them, a portion of fixed alkaline falt. A fresh pumpkin, which weighed 200 ounces, being cut into flices and dried in the fun, loft in nine days 100 ounces of its weight; the remaining 10 ounces being reduced to ashes, did not yield one ounce of earth. Had Van Helmont reduced his willow to ashes, I think it would not have yielded one pound of earth; this small quantity of earth, added to the uncertainty there is as to the earth, wherein the willow was planted, being equally free from moisture when it was weighed, before and after the willow had acquired its increase, renders the conclusion which is drawn from the experiment wholly questionable.

Count Gyllenberg, in order to prove that vegetables derive all their conflituent parts from water, even their oils and falts, as well as their earthy particles, makes the following observation.—" Four thousand different plants can grow in twenty pounds weight of earth, and in each of them shall be found a different oil and a different falt. Ler us suppose these plants to be chemically anylized, near an ounce of oil and falt will be found in each. If this oil and this falt had proceeded from the earth, there must have been in that earth four thousand ounces, or 250 pounds of oil and falt, whereas in fact there was not a grain of either

Hed ffrom the followers which rights in

<sup>\*</sup> Count Gyllenberg's Elements of Agriculture, translated by Mills, p. 72—This work is attributed by Mr. Mills to Count Gyllenberg, by the French translator to Wallerius; see the Ed. quoted in Vol. II. p. 76.

of them in it." This observation does not prove, that fimple water is converted into earth, or falt, or oil by vegetation; it merely shews, that plants by vegetating acquire fuch an increase of weight, as cannot be derived from the earth in which they grew, and become bodies, whose constituent parts are different from both earth and water: but it neglects the confideration of two fubflances, as necessary to vegetation as either earth or water-light and air. The air is a fluid whose constituent parts are not yet fully ascertained; besides water, there are reasons to think that it contains an oily and a faline principle; and as to light, opticians have discovered not only that the same ray of it has different properties on its different sides, but that it is by no means an homogeneous fluid, though no experiments have yet sufficiently shewn, whether that sluid be a saline or phlogistic substance, or both. The rays of the fun feem to be acted upon by every body in nature, and they may be capable of being combined with air, or water, or earth; and in that state of combination they may enter as constituent parts into vegetables, &c. form airs, falts, and oils of varous kinds. There may be an igneous and elastic sluid, as well as an aerial one univerfally dispersed, and on which the fluidity of the air itself may depend; and this fluid, being imbibed by vegetables, may be a principal component part of them, and being restored to its sluidity by combustion, fermentation, and other causes, it may produce heat or flame, according to the circumstances under which it endeavours to discharge itself. There is a curious experiment which will illustrate the efficacy of air and light in promoting vegetation.

Mr. Eller took a large quantity of water which had been twice distilled, and having filled a cylindrical glass vessel with it, he bound a sheet of paper over the mouth of the vessel, and set it in the sun in the middle of summer for several weeks. He soon observed that the water began to be troubled, that it emitted small bubbles, that its surface became

SWATPLA SE

became fomewhat frothy, and that the bottom of the vellel was covered with a green matter. He afterwards distilled the water, and from the last portion of it, containing the green matter, he obtained an acid and an oil, and though he does not mention it, there remained, probably, a portion of earth. I remember having seen a glass tube, which, after having been hermetically fealed and nearly filled with water, had been left for some months on a table on which the fun occasionally shewn, that side of the tube on which the rays of the fun had fallen, was covered with green matter, whilst the other side was free from it. Dr. Priestley, with his accustomed ingenuity, has investigated the nature of the green matter which is thus formed, and shewn that it is a vegetable, whose feeds are constantly floating in the atmosphere, and that light is absolutely requilite to its production, mere heat not being sufficient for the purpose; but that light itself will not produce it in water which has no communication with the air; probably because in that case the water is deprived of the seeds from which the vegetable fprings, and hence we may infer, that the action of the fun's light is not alone fufficient to gene-rate falts and oils in water, though it be infirumental in enabling the feed of the vegetable to expand itself into the form of a plant. The vegetable thus formed, certainly contains more acid, more oil, and more corth, than existed in the feed from whence it fprung, but it would be a rash conclusion to fay, that simple water has been converted into any of these substances, though it seems to be a just one to fay, that stakes the many of these stakes are though it seems to be a just one to fay, that stakes the many of these stakes are the stakes are one to thy, that either the water, or the air in the water, or the folar light, have jointly or feverally been changed into them. It it pullible fo far to purify a portion of utmofpherical air from the fmall feeds of vegetables, that dif-tilled water, though in contact with this purified air, and exposed to the action of the folar rays, shall not produce any green matter, or undergo fach a change, as to yield by distillation, other a faline or an oily principle i—I have sow given an account of the most noted arguments which

have been brought in support of, or in opposition to the doctrine of the transmutation of water into earth, and I am forced to conclude, from this view of the fubject, that the question is not clearly decided either way: as to my own opinion, I beg leave to fay, that I am rather disposed to believe that water is converted into earth, though I own that no experiment has yet been produced, to which reafonable objections may not be made. The point I am fenfible cannot be decided by authority; yet I will put an end to the disquisition by mentioning the opinion of Newton. Vegetabilia comia ex liquoribus omnind crefcunt, dein magna en parte in terram aridam per putrefactionem abeunt, et limus en liquoribus putrefactis perpetud decidit. Hinc moles terre arride indies augetur ; et liquores, nifi aliunde augmentum sumerent, perpetuo decrescere deberent et tandem deficere".

## ESSAY XXXVI.

subic factor different large of a

Of Westmoreland State, and some other Sorts of Stones.

WE have in the mountainous parts of Westmoreland, various forts of slate; all of which are used by the inhabitants of that county for covering the roofs of their buildings; and the best of them are either carried by sea to London, Liverpool, Hull, and Lynn, or by land into the bishoprick

Newtoni Oper. Vol. III. p. 157. Ed. Horsley.—Busson, another philosopher of no small eminence is of opinion, that the elements may be changed into each other, and that water may even become air. "Comme je suis tres persuade que toute la matiere est convertible, et que les quatre elemens peuvent se transformer, je serois porté a croire, que l'eau peut se transformer en air lorsqu' elle est assez rarisse pour s'elever en vapeura." Suppl. Vol. I. p. 100.

bishoprick of Durham, Cumberland, Northumberland and Lancasbire. The different sorts of slate are distinguished from each other by the sineness of their grain, by the thickness into which they are split, by their colour, and by their weight. The most general colour is blue; there are many shades of it from a very pale to a deep blue. The blue of some slates has a greenish cast, this is very observable after a shower in a building which has been recently slated, if any of the greenish slates happen to have been used along with the blue. We have also a purple slate, and one which is nearly black, or at least is so dark, that it is used for writing on. With respect to the comparative weights of different sorts of slate, the following table, which was made with sufficient care, will give the reader some notion of the subject.

## Weight of a cubic foot of different forts of flate.

ESSAY XXXXII.	Ounces.
Purple flate, Kentmere near Kendale	2797
Pale blue, Coniston Water Head	2791
Dark blue, Troutbeck	2781
Pale blue, Throng Crag	2780
Pale blue, White Moss	2779
Deep blue, Old Cauldron	2778
Pale blue, greenish, near Ambleside	2768
Pale blue, Ingleton, Yorkshire	2767
Dark, writing flate, Bannefdale	2765
Blackith, used for flooring, Head of Winander Mere	2758
Deep blue, Longdale -	2752
Greenish blue, Kentmere	2750
Blackish, Cartmel, Lancashire	2740
Very pale blue, fine grained Amblefide	2732
	No.
Medium weight of a cubic foot	2767
AND COUNTY OF THE PROPERTY OF	C. A. Commission

I have not in this table included all the varieties of flate which may be met with in Westmoreland; but it is not probable

above

probable, that those which I have omitted differ more from each other, than these which I have mentioned do, either with respect to colour or weight. Wallerius speaks of a bluish slate which weighed 3300 ounces to the cubic foot; this fort, probably, contained a large portion of iron; the bluish iron stone, called Catscope, weighs 3300 ounces to the cubic foot. In the slate quarries, some of the sissures are filled with spar which has often an iron or copper pyrites adhering to it; in the very middle of the blocks of slate there are many little hollows, each of them big enough to hold a large hazel nut; these hollows are filled with clay and in one of the quarries I saw a considerable quantity of clay sit for pipes, between two layers of slate.

It appears from the table, that the difference in weight between a cubic foot of the heaviest, and a cubic foot of the lightest of the fourteen forts of slate there enumerated, is only 65 ounces; or about one forty-third part of the weight of a cubic foot of the heaviest fort; hence, supposing the different forts of slate to be split to equal thicknesses, the difference of the weights sustained by the timbers of slated buildings, is very inconsiderable, whatever fort of slate be used.

That fort of flate, other circumstances being the same, is esteemed the best, which imbibes the least water; for the imbibed water not only increases the weight of the covering, but in frosty weather, being converted into ice, it swells and shivers the slate. This effect of frost is very sensible in tiled, but it is scarcely felt in slated houses; for good slate imbibes very little water; and when tiles are well glazed, they are rendered in some measure, with respect to this point, similar to slate.—I took a piece of Westmoreland slate, and a piece of a common tile, and weighed each of them carefully; the surface of each was about 30 square inches; both the pieces were immersed in water for ten minutes, and then taken out and weighed, as soon as they had ceased to drip; the tile had imbibed

above a seventh part of its weight of water; and the slate had not imbibed a two hundredth part of its weight; indeed the wetting of the slate was merely superficial. I placed both the wet pieces before the sire; in a quarter of an hour the slate was become quite dry, and of the same weight it had before it was put into the water; but the tile had lost only about 12 grains of the water it had imbibed, which was as near as could be expected the very quantity which had been spread over its surface; for it was the quantity which had been imbibed by the slate, the surface of which was equal to that of the tile: the tile was left to dry in a room heated to 60°, and it did not lose all the

water it had imbibed in less than fix days.

Some of our old buildings in Cambridge are covered with a whitish kind of slate, which is dug at Collyweston in Northamptonsbire; this flate is, as to its principal component part, a calcareous earth, very fimilar to the Barneck stone of which Peter borough cathedral and part of King's Chapel in Cambridge are built; and the stratum of stone, which may be feen on the road fide between Ouford and Burford, and from thence towards Gloucefler, is not very different from it. This Collyweston state imbibes more water, and retains it for a longer time, than the Westmoreland flate does; but it does not imbibe half fo much, nor retain it a quarter of the time, that a common tile does. The manner of its being formed into flate del lerver to be noticed. Large blocks are dug in autumn, and these blocks being placed in a polition different from that they had in the quarry, the rain infimutes itself between the layers of which the stone is composed; and in frosty weather the water swelling, as it becomes ice, splits the block of stone into plates of a proper thickness. We have a stone which is of a calcareous nature, and is called church, in this neighbourhood; it is foft and easily wrought, and when properly placed in a build-ing is very durable; but if the position of the stone in the building, be different from what it was in the quarry, that 00000

is, if the fide of the stone which in the quarry was parallel to the horizon, be either perpendicular, or inclined to it, in the building, it soon cracks and moulders away; and I am not certain but the durability of Portland stone itself, may have some dependence on its position in a building, being similar to or dissimilar from that, which it had in the quarry: and this may be one reason why we see in Black Friars bridge, and in some houses and other edifices in London, which are made of Portland stone, a few stones which are more decayed than the rest.

The stone or metal, as the workmen call it, of which the Westmoreland slate is made, though it does not split equally in all directions, yet is it not formed into slate by the action of the frost, as the calcareous slate of Northamptonshire is: it is dug, or blasted from the quarry in large masses, and split by workmen surnished with tools suited to the purpose. Though the weights of equal bulks of the different forts of Westmoreland slate, do not differ much from each other, yet all the forts are not equally capable of being split to an equal degree of thinness: the quality of the slate varies also with the depth of the quarry, that being the best which is raised from the greatest depth.

We learn from Dr. Borlaje\*, that the gray blue flate of Donyball in Cornwall, weighs only 25 12 ounces to the cubic foot, which is greatly less than the lightest of the Wostmoreland states, that I have met with. This Cornish state for its lightness and enduring weather (though I have no reason to think that in the last particular it excels the Westmoreland state) is generally preferred to any state in Great Britain, and "is perhaps the finest in the world+." This fort is split to about the thinness of an eighth of an inch, when it is applied to the covering of a roof, and it then weight rather more than 26 ounces to the square foot:

Vol. II.

<sup>#</sup> Hift. Corn. p. 93.

<sup>†</sup> Woodward's Cat. Vol. II. p. 5.

the very pale blue, fine grained flate from near Amblefide; when an eighth of an inch in thickness, weighs about 28 ounces to the fquare foot, or about 2 ounces more than the

Cornish state here spoken of dans and and an analysis and

The finest fort of blue flate is fold at Kendale for 3s. 6d. a load, which comes to 1 f. 15 s. 2 ton, the load weighing two hundred weight. The coarfest may be had for 2 s. 4 d. a load, or 1 f. 3 s. 4 d. a ton. Thirteen loads of the finest fort will cover 42 square yards of roof, and eighteen loads of the coarfest will cover the same space: so that there is half a ton lefs weight put upon 42 square yards of roof when the finest slate is used, than if it was covered with the coarfest kind, and the difference of the expence of the material is only 3 s. 6 d. To balance in some measure the advantage arising from the lightness of the finest slate, it must be remarked, that it owes its lightness, not so much in the component parts of the stone from to any diversity in the component parts of the workmen which it is split, as to the thirmess to which the workmen reduce it; and it is not able to refift violent winds fo well

as that which is heavier. Or that going to stand which is heavier than a covering of fine flate, but not greatly for Thirteen loads or 26 hundred, weight of fine flate will cover, as has been observed, 42 square yards : when plumbers cast sheet lend for covering of honses or churches, they feldom run it thinger than to about y they make, or should make, the least a pound in a signare foot thicker, than when it is used in places not exposed to the meridian sun; for the power of the sun in acaleining lead is very great; in the toroid zone, a least covering of the ordinary thickness will not last above size or six years, before it is calcined into a white pellicle resembling white lead. In a sheet of says lead these is a great inequality in the thickness of the several parts of it; if the abimest spare weighs 7lb, to the square soot, the thickness part mill often weigh 9lb.; let it be supposed then, that a sheet of east

P Codward Lat Vel IL

lead, the thinnest part of which weighs 7lb., weighs at a medium 8lb. to the fquare foot; then will a fquare yard, or nine square feet, weigh 72 pounds, and 42 square yards will weigh 3024 pounds, or 27 hundred weight; which is one hundred weight more than the weight of the flate. But this is not the whole weight of the lead which is requifite to cover 42 fquare yards, an addition is to be made to it, equal to the weight of the lead which is used in lapping one sheet over another. Milled lead may be not only rolled out to a greater thinness, than sheet lead can possibly be cast to, but it has also a much greater uniformity of thickness, than cast lead. The plumbers fay, that milled lead may indeed form a lighter and more uniform covering than sheet lead, but that it will not last so long. I know not how that may be, but the milled lead company, near 100 years ago, offered to enter into a covenant to keep a covering of their milled lead of 7lb. to the fquare foot, in good and constant repair, for a term of 41 years, at 51. a year, for every covering of 100f. in value. A term of 41 years is not a quarter of the period which many coverings of Westmoreland flate have lasted with very inconsiderable repairs; and as a ton of flate will cover a larger furface than a ton of lead, and does not cost in any part of the kingdom, to which there is water carriage, one fourth of the price of the lead. it feems as if it might be generally used instead of lead with very great advantage.

In Rulia they cover their houses with iron, and in Sweden with copper; and some architects have been fond of introducing the tile of copper covering into Great Britain. I have no knowledge of the duration of a copper covering; but I should conjecture, from the thinness of the copper which is used for the purpose, that it would not last so long as state; it has certainly the advantage of being much lighter, and where there is danger of straining the walls by the weight of timber in the roof, it may be used with great advantage. All the plates of copper of sour feet in length and two in breadth, which weigh less than 10 pounds, are,

Nn2

called thatch copper, from their use in covering buildings; these plates are in general a penny in the pound weight dearer than the thicker plates, on account of the greater trouble in rolling them. A square foot of thatch copper does not weigh quite 20 ounces, and hence 42 square yards of such copper will not weigh much above four hundred weight, and its thickness will be about the fortieth part of an inch.

A common cambridge tile weighed 37 ounces; they use at a medium 700 tiles for covering 100 square seet, or above  $2\frac{1}{2}$  tons of tile to 42 square yards. Hence, without including the weight of what is used in lapping over, &c. when a building is covered with copper or lead, it will follow, from what has been said, that 42 square yards of building will be covered by

Copper - - 4 hundred weight.

Lead - 27 Coarfor flate - 36

The Northamptonshire slate (not to speak of several other sorts) not being sold by weight like that from Westmoreland, nor having a definite size like tile, it is not an easy matter to estimate the weight of it which is requisite to cover 42 square yards, or any other definite surface; a cubic soot of it weighs 2592 ounces, so that it is, bulk for bulk, near one twentieth part lighter than the lightest of the Westmoreland slate, but its thickness is, at a medium, much greater; hence its weight in a definite surface of roof, is greater, I apprehend, than that of the coarsest kind of Westmoreland slate; its durability is very considerable, as may be collected from the time it has lasted on some of our college buildings.

A common flate is a very compound body; it contains iron, to which it owes its colour, calcareous earth, magnefia, flint earth, and clay combined in different proportions in the different forts. Mr. Kirwan is the only person who

has

370

has analyzed any of the forts: the fort he analyzed was the bluish purple, which is principally used in London, and which is brought thither from Devonshire and Wales. A cubic foot of it weighed 2876 ounces, which is near 150 ounces more than the weight of a cubic foot of the finest fort of Westmoreland slate: he found that 100 grains of it confisted of about 46 grains of flint, 26 of clay, 8 of magnefia, 4 of calcareous earth, and 14 of iron, and that it

loft, by being heated red hot, 2 grains,

I took a piece of Throng Crag slate, which is the fort Newgate is covered with, weighing 446 grains, and heated it red hot; it had loft 4 grains of its weight, by that degree of heat; I kept it for half an hour in a red heat, it had then loft 38 grains of its original weight; I continued it in the fame heat for three hours more, and it had then loft 43 grains, or near one tenth part of its weight. I calcined the bluish green Ambleside slate in a degree of heat, which would have reduced the fame weight of calcareous earth to lime; 446 grains of it lost 41 grains; on a repetition of the experiment, I found that 446 grains had loft 42. The fame weight of White Moss slate, treated in the same way. lost 42 grains; and the same weight of slate from Coniston loft 44 grains. I tried feveral other flates in the fame manner, and the general conclusion is, - that Westmoreland flate loses, by being calcined in a red heat for feveral hours. about one tenth part of its weight.

All these slates, when reduced to a fine powder, are acted upon with great violence by acids, a confiderable portion of fixed air is discharged, and a calcareous earth is dissolved in the acid. I poured a diluted acid of fea falt on 446 grains of Throng Crag slate in powder, 30 grains of fixed air escaped during the folution. We have seen that the fame weight of the fame fort of flate loft by calcination 43 grains, the difference is 13 grains; but whether these 13 grains are water, or a part of the earthy fubstance of the flate which is driven off during the calcination, is what I do not pretend to determine. N n 3

The calcined flate being put into water, there is formed in a few days a strong lime water; this water deposites, as other lime water does, an earth which effervelces with an acid. It has been proved, in the Essay on calcareous earths, that 20 parts of calcareous earth contain about o parts of fixed air; and hence, as the flate is supposed to lose about one tenth of its weight of fixed air by calcination, the crude calcareous earth (fuppoling the air to have proceeded folely from calcareous earth) which it contains, may amount to about 22 parts in an 100 of flate. I have met with some flate, much resembling the Westmoreland slate. which does not lose above a twenty-fifth part of its weight by calcination. Beds of limestone are generally incumbent on the beds of flate; and, however philosophers may account for the original formation of these beds, it may easily be admitted, that the component parts of the upper stratum may be mixed with those of the lower; and if the fact was examined, I think, it would be found, that the flate is more mixed with calcareous earth, the nearer it approaches to the limeftone ftratum.

I distilled five ounces of White Moss flate in a very fire for three hours; there came over a great deal of air but scarce a drop of water, (though it is possible that in this, and other distillations of a like kind, some water may escape with the air,) and there was a slight fmell of fulphur. The mass remaining in the retort was reduced into a black cellular glass, of fo hard a texture, that it struck fire with steel; it adhered so much to the retort, that I could not seperate it so perfectly as to be able to fee what loss of weight the flate had fuffered by being vitrified. We have no coal in Westmoreland, except a little of a bad quality near Shap, or glass-bouses might be established at the state quarries with great prospect of advantage; for though the materials of which battle glafs is made, cost but little in any country, yet there they would cost nothing. Very good glass might, probably, be made from the slate alone, for the cellular texture would disappear, either on keeping the glass longer in the fire, or on remelting it; but certainly it might be made from the slate mixed with fern ashes, or with kelp ashes, or with other substances containing fixed alkali:—this hint, I hope, will not be given in vain.

Pliny speaks of a kind of fossil glass, which one Obsidius, he fays, found out in Ethiopia; it was of a black colour, and fometimes transparent: and Herodotus, in the third book of his history, reports, that the Ethiopians had a cultom of drying the carcales of their dead, of covering them. when dried with gyplum (or plaster of Paris (yudwandes) of painting their portraits on the plaster, and, lastly, of depositing them in cells made of transparent glass, which in that country was dug in great plenty. This account has been looked upon as fabulous; because glass, it is said, is not a natural but a factitious fubstance; and the learned, for the fame reason, have been much puzzled about Pliny's lapis Obfidianus, or, as fome will have it, opfianus, on account of its transparency. The word (man in Herodotus) here rendered glass, may, perhaps, denote lapis specularis; which is now, and has in all ages, been dug out of the carth, and is found frequently along with gypfum; I do not believe, indeed, that it has been ever found in pieces large enough to make coffins of : but, supposing it to mean glass strictly so called, I see no difficulty at all in admitting the existence of fossil glass. A subterraneous fire, of a proper degree of Arength, would convert a Aratum of Westmoreland slate into a vitreous mass of a black colour. Nor is Westmoreland slate the only substance which might be converted into fossil glass; the gray rag stone, before mentioned\*, admits a fimilar change; fo does the blue whin-flone, and the Derbyshire toadstone, and several other forts of stones. The reason of the fusibility of these stones. is explained, in some measure, by an experiment related in another place +; it is there proved that two species of

earth, separately unvitrisiable, may be vitrisied when mixed together; the two earths there mentioned are clay and chalk, but the observation is true concerning some other earths. Now the slate and stones, of which we have been speaking, are all compound bodies, consisting of silicious, argillacious, calcareous earths, &cc. combined in different proportions, and the fusibility arises from their mixture.

Some reasons have been given (though I do not think they prove the point) for considering the Derbyshire toadstone as a species of lava, which has undergone a semi-vitrisication; however that may be, I have met with pebbles (rounded, probably, by ante-diluvian waters) which resembled toadstone in colour, weight, and consistence, in the gravel-pits of Cambridgesbire; in the marl-pits of Chesbire; in the clay which is situated under the grit, and above the spale of Derbysbire; on the sides of the mountains, and in the beds of the rivers of Westmareland: and I doubt not similar ones will be detected, by siture observation, in many other places.—The sollowing table cost me some trouble in the making, I am unwilling that it should be lost, and there are some readers who will be gratissed with a sight of it.

No. 1. Guernsey pebble, from the pavement of one of the streets of Westminster. 2. I met with this stone on Hale-Fell, near Beetham, in Westmoreland; it is of a darkbrown colour, and admits a very fine polish, but it is not calcareous. The block was some tons in weight, and situated on the furface of the earth, every where furrounded with limestone rocks; I think it was a block of basaltes, in which many crystals of black shoers were to be seen. 3. Dark gray cobble, from the gravel-pits near Cambridge: it much refembles No. 4. Dark gray toadstone from Derbyshire; free from those sparry specks (which in mouldering. away by exposure to the air, often leave the toadstone as if it was worm-eaten) and striking fire with steel. 5. Lead coloured cobble, with black specks, and of a vitreous texture, from Hearfam Head, in Westmoreland. Hearfam Head is a hill composed of calcareous strata; but there are found on its furface, and in other parts of the county, detached round pieces of a blue rag-stone, of granite, and of

of a very hard compound stone, called by the masons of the country callierde; probably so denominated either from the earth (erbe) of which it is composed, refembling fline (caillou) in hardness, or from its being composed of different forts of earth coagulated (caille) together. Mineralists, I think, would class the callierdes, for they are not all of the fame kind, amongst the porphyries, bornstones, &c. 6. Similar to toadstone in texture, but darker in colour, from a marl-pit near Tabley, in Cheshire. 7. Much the same as the preceding, a large block found in a field near the mills at Millthrap, in Westmoreland. I do not venture to call these two last stones volcanic productions, yet the surfaces of them looked as if they had been formed by the cooling of the mass. 8. Round toadstone pebble, from a bed of clay under the grit stone in Derbyshire; I write this only from recollection of its appearance; I may have mistaken a blackish limestone for toadstone. o. Purple slate, Kentmere, near Kendale; the heaviest of any of the Westmoreland flates, but not fo heavy as the purple flate used in London. 10. A callierde with a deep green ground, and specks of a lighter green, from the fea shore near Lancaster. I have feen these callierdes in various other parts of Great Britain, but I do not know whether we have any strata in the Island which could have furnished them. 11. A greenish cobble, of an uniform texture, gravelpit in the road from Cockeran to Lancaster. 12. Like No. 10. marl-pit, Cheshire. 13. Blue whin-stone from Scotland; in a fire which would convert an equal bulk of marble to lime, a ton of whin-stone would lose 21 hundred weight. 14. Greenish cobble, Wierfide, Lancashire: this and No. 11. have some resemblance to Westmoreland slate, but I do not know where the stratum is situated that has furnished these detached pieces. 15. Blue rag-stone, forest near Mansfield. 16. Granite from Aberdeen. A cubic foot of Guernsey pebble (No. 1.) contains, it is evident, above 200 ounces of matter more than is contained in a cubic foot of Aberdeen granite; but from

from that circumstance alone it must not be inferred, that a pavement made with Guernsey pebbles, will last longer than one made with Aberdeen granite: for the durability of a body exposed to friction, does not depend so much on the number of particles which enter into its composition, as on its hardness, or firm adhesion of its parts. But in bodies equally hard, that will last the longest which contains the greatest quantity of matter in a definite bulk; and hence supposing the Guernsey stone to be only as hard as the Aberdeen granite, it must last longer when exposed in the streets to the friction of the carriage wheels; on inquiring into the fact, a paviour told me, - that the Guernfey pavement was a very bad pavement for a poor man-because it feldom wanted repairing. 17. Gray blue rag-flone, Westmoreland. 18. The fame after being calcined to a red colour. 19. Gray rag-stone from Ilvay crag, near Millthrop. 20. The same calcined to a red colour. - These ragstones, I apprehend, lose somewhat of their weight by calcination, but, their bulk being diminished in the same proportion, their denfity or specific gravity remains nearly unaltered; in a stronger fire they are changed into a blackish glass. 21. Shale-bind. This is the name of a stratum, consisting principally of calcareous earth impregnated with bitumen. which is fituated both above and below the beds of fale in Derbyshire. The bind is various in thickness from a few inches to fome feet: one fort of it is called by the miners treacle bind, from their finding lodged in its cavities a bitumen of the colour and confistence of treacle; this bitumen is most abundant where there is the greatest quantity of shale incumbant on the bind. There are in the stratum of bind many round stones called, probably from the rotundity of their figure, boulders; some of which weigh only a few ounces, other half a ton. Whether all round stones, met with in the strata of the earth, or upon its surface, have received their figure from the action of water is uncertain; but that many of them have, the fituation in which they are found, will not fuffer us to doubt. Not far from Pon-

typool there is a large mountain, the bottom of which is washed by the river U/k; this mountain contains coal and iron stone. At Newport a considerable trade is carried on with coal, which has been washed from the sides of this and other mountains by the river: the coal is found in the channel of the river, in round, flat, smooth pieces; so perfectly refembling in shape river pebbles, that they clearly indicate the manner in which these pebbles have been formed. 22. What some call white toadstone, Youlgrave, Derbyshire. 23. Brown quartz pebble, from the forest between Mansfield and Newark. 24. Black pebble with red fpots. fame place. 25. Reddish rag-stone, Helm-End, near Kendale. 26. Pennarth limestone, washed in large cobbles from the clifts on the Welch fide of Briftol channel; the lime made from it is highly effeemed in that country from its fetting under water; it is called lion lime (perhaps lien) from its binding quality: the stone is of a gray colour, and, befides the proper earth of lime, contains a large proportion of clay and iron. 27. Transparent white quartz, gravel pits. near Cambridge. 28. Transparent white quartz, forest about Mansfield. 29. White opake quartz, fame place. The crystals, called Bristol stone, are esteemed the purest fort of quartz. It is commonly known that two pieces of quartz, when rubbed together in the dark, emit a phosphoric light, accompanied with a strong smell. The difference between quartz and common flint, confifts not fo much in the colour, for both quartz and flint are of various colours, as in this, that quartz (though it be not perhaps an absolutely pure filiceous earth) contains a less proportion of clay and calcareous earth, than flint does. I have observed on the sea coast at Turmouth, quartz pebbles beginning to be decomposed, and verging towards the state of a white argillacious earth: most of the fand in every part of the world confifts of quartz or flint in powder; and, as matter is infinitely divisible, the imagination can fet no bounds to the minuteness of the grains of fand;

torob as as tuling the New

but I have fometimes doubted, whether, after they are reduced below a certain standard, they may not constitute fome other species of earth. 30. Granite, from the marlpits in Cheshire. The roads in many parts of Lancasbire and Cheshire are paved with granite, and other hard round pebbles, which are found in their marl-pits, or fetched from the Welch coast; the pavement costs a thousand, or twelve hundred pounds a mile in making. 31. Granite, from a large block near Dollam Tower, in Westmoreland. Large maffes of a reddifb granite are found on the fides of the hills, in the vallies, and in the beds of the rivers, not only about Shap, but in various other parts of Westmoreland. It is a question of no small difficulty to account for the manner of their being placed there: fome will have it that they have been left there by water; and others think they have been ejected from the bowels of the earth by the force of a volcanic explosion. Beds of granite are found in many, and detached pieces in most parts of Europe. The highest mountains on the globe are formed from the lowest ftrata of the earth, and the tops of the highest mountains are composed of granite; and hence granite mountains are called primitive mountains; inalmuch as the strata of granite, being fituated below the strata of rag-stone, shale, limestone, &c. of which many other (called fecondary) mountains are composed, must have existed before them. All granites are compound bodies, they confift of two, of three, of four, or of five distinct substances denominated, by writers of fystems of mineralogy, quartz-felt sparmica featites and floerl. It belongs to the higher chemistry to analyze the component parts of granite, to explain their origin, and the manner of their combination; and to enquire whether they are subject to a spontaneous, feparation, and what kinds of fubstances will arise from a stratum of decomposed granite. 32. Red granite, from a Cheshire marl-pit, resembling the red oriental granite. All the varieties of red and gray granites, which may be feen

in the works of the ancients remaining in Italy, might be found, I believe, in different parts of Great Britain; without any thought of making a collection of them. I have accidentally picked up near twenty different forts. 33. Shale from Derbyshire. 34. Quartz, white, with many small irregular holes: there are quarries of it in France, and we import mill-stones made of it. The holes are remarkable; it looks as if the stone had been worm-eaten; but the holes are formed, I conjecture, from fome of the principles of the stone being decayed, whilst the rest remain intire. I have frequently feen pieces of rag-ftone, and even fome forts of granite, which have been externally, and indeed to a very fensible depth below the surface, studded with little holes from the same cause. 35. A cellular lava, of which the mill-stones, called Rhenish, are made; it is very porous, of a brown dirty colour, and in external appearance like a piece of coak, but it is hard enough to strike fire with steel. Strabo, in speaking of an eruption of mount Etna, very accurately describes the formation of this species of stone, which in his time was applied to the same purpose it is now; I quote the Latin translation of the passage -lapide in crateribus colliquato ac deinde furfum egefto, bumor vertici superfusus conum est nigrum, per montem deersem fluens : deinde ubi concrevit, lapis fit molaris\*.

The analyzing the various stones which are met with, either in large beds in the earth, or in detached pieces at the bottoms of the rivers, or on the sea coasts of the kingdom; and the lodging the specimens in some public Receptacle, where they might be seen by the Students in Natural History, might occupy very usefully the leisure of a philosophical Chemist. He would find a far greater variety of jaspers, porphyries, granites, flints, limestones, slates, lavas, &c. than at the first view of the subject he would probably expect. Experimental investigations of this fort, made with ability and caution, in different parts of the world,

are the only fure foundations on which we can ever hope to build any probable fystem concerning the formation of mountains, the antiquity of the present form of the globe, and the causes of the vicissitudes which it has undergone. It is the proper province of natural philosophy to explore fecondary causes; they are the steps on which the mind of man ascends from Earth to Heaven: for the more distinctly we apprehend the number and connexion of the fecondary causes operating in this little system which is submitted to our view, the more certainly shall we perceive the necessity of their ultimately depending, like the links of Homer's chain, on a FIRST.

Valentine for his commendation of every antimonial preparation, i. 9.—his notion of fire, i. 62.—mistaken as to the degree of cold in which animals can live, i. 102.—produced 28 degrees of cold by dissolving sal ammoniac in water, i. 325.—account of his experiments on quicksilver, ii. 501.

Boles, places in Derbyshire where lead has been smelted without the assistance of a bellows, i. 371.—how situated, i. 372—a pig of lead smelted in the time of Adrian, dug up at one of them in 1766, ibid.—this method of smelting not gone out of use in the last century, i. 371.

Bomare, mistakes the meaning of the word ærofus, ii. 450.

Books, alchemical ones, all ordered by Diocletian to be burned, i. 6.—above 5000 on alchemy published fince his time, ibid.—near 1000 published by the feveral philosophical societies in Europe since 1665, i. 15.

Brass, how made, ii. 430.—increase of weight obtained by the copper used in making brass, ii. 434.—increase depends on the quality of the copper, ibid.—old brass mixed with the composition used for making brass improves its ductility, ii. 434.—malleability of, injured when made with pit-coal, ii. 435.—made with black-jack, ib.—for many purposes more usful than copper, ibid.—changed by fire into copper, ibid.—varieties in the colour O o 3

of, to what owing, ib .- weight of a cubic foot of Briftol plate brass, and of brass which had been long exposed to the fire, ii. 436.

method of making quite pure, ii. 439—made from melting zinc and copper together, ii. 432.—and by combining the vapour zinc and copper together, ii. 432.—and by combining the vapour of zinc with copper, ii. 439.—not necessary to have it pure in many manufactories, ii. 440.—manufactory of, history of its establishment in England, ii. 441.—exportation of, prohibited by statute in the reign of Hen. VIII. ii. 443.—bill for repealing that statute passed by the Commons in 1783, ibid.—and thrown out by the Lords, ii. 444.—reasons for throwing it out, ibid.—English unwrought brass allowed to be imported, free of duty, into various countries, ii. 445.—trade of making of, will probably be much assessed by a late agreement of the copper companies, ii. 446.—making of, not a modern invention, ii. 448.

Braun, account of his discovery of the congelation of quickfilver.

Braun, account of his discovery of the congelation of quickfilver,

i. 102.

Brazil—bras lumps what, i. 75.

Brine springs, the strongest yield one sourth of their weight of salt, i. 153.—met with in Cheshire, Worcestershire, Staffordshire, &cc. ibid.—advantage of strengthening weak brine or sea water and salt salt applained in 154.—concentrating weak brine by frost by rock falt, explained, i. 154.-concentrating weak brine by frost recommended, i. 191.

Bury, St. Edmund, heat of the springs there, i. 344.

mand Corches the de flates - percay to them, the

Cadmia of Pliny, what, ii, 449.

Calamine an ore of zinc, ii. 415.—derivation of the term, ii. 416.—where found, ii. 417.—formerly exported from Great Britain as ballaft, its use now well understood, ibid.—quantity annually raised in Derbyshire, ii. 418.—Derbyshire calamine cheaper than that of Somersetshire, ibid.—loses one third part of its weight by folution in the acid of vitriol, and by calcination, ibid.—all forts of calamine do not lose of their weight by folution, ii. 421.—method of dressing it for the brass-makers, ibid.—formerly thought to contain no metallic substance, ii. 423.—reason of the mistake, ibid.—zinc obtained from it by Marggraf, ii. 424.—used by the ancients for the making of brass, ii. 452.

Callierde, what, ii. 540.

Callierde, what, ii. 540.

Cannon, brafs, composition of, ii. 462.—cast at Woolwich, ii. 463.—price per ton of, casting there, ibid.—thickness of, at the mazzle, and at the touch-hole, ii. 464.—gives a louder report than iron cannon, ib.—why not east of copper alone, ibid.

fire lead mines in, have afforded much filver, i. 389.
from what prepared, ii. 500.
weight of a cubic foot of, i. 19.

## I NE DI E X

Celt, British instrument, use of Juncertain, ii. 437 weight of a cubic foot of, ib.—melted gave indications of containing zinc, ibid.—contains no lead,—weight of a cubic foot of, after being is and disk with Ited. ib.

melted, ib.

Celtiberians, their method of hardening their arms, i. 84.

Charcoal, emits neither vapour nor fmoke during combustion, i. 67.

distilled with viotriolic acid, yields sulphur, and is reduced to ashes, i. 69.—manner of making of, i. 279.—quantity obtained from equal weights of various wonds by the same degree of heat, i. 283.—attracts in cooling something from the sir, i. 283.—attracts in cooling something from the sir, i. 283.—attracts in cooling something from the sir, i. 284.—
62 pounds of it being burned yield, according to Van Helmont, 61 pounds of an elastic vapour, called first by him Gas, ibid.—different accounts of the quantity of ashes procured from the burning of charcoal, i. 285.—the difference accounted for, ibid.—atmospherical air rendered destructive of life by passing through red hot charcoal, or by charcoal being burned in an apartment in which there is not a supply of fresh air, i. 288.—Rossa method of recovering persons sufficested by sumes of charcoal, ibid.—ten cubic inches of air reduced to nine by being passed through red hot charcoal, i. 289.—not decomposed by long exposure to air and water, i. 292.

Charring of wood used in soughs and mines recommended, ibid.

Chemistry, history of, its rise and progress, i. 1, &cc.—derivation of

Chemistry, history of, its rife and progress, i. 1, &cc, derivation of the term, i. 27.

Cherry-Hinton, heat of the spring there at all seasons, i. 344.

Chert, found at Bakewell in Derbyshire, use of, i. 233.— Substitute for flints, 1. 234-

· Chimney, borizontal, for the finelting of lead ore recommended,

China, oriental, component parts of, i. 237.— substances in Great Britain resembling its component parts, i. 238.— German as unvitrifiable as the criental, i. 239.—weight of a cubic foot of oriental china compared with that of Flint ware, yellow ware, Bristol

Christalinaria, what, i. 34—owing either to a diminution of the mentruum, or of the heat in which a body is dissolved, i. 34—water of, what, i. 48. water of, what, i. 48.

Tylal, term whence derived, i. 34.—ancients supposed took crystal to be congested water, ib.

The confidence of pit-coal increases in weight by exposure to the air, i.

Cinnabar, an ore of quickfilver, ii. 500.—levigated becomes vermilion, ibid.—finest fore from Japan, ibid.—Clay, estimated by the way

# LNIEX

Clay, fine white, contains above half of its weight of fand, i. 231.

conflictutes the basis of all earthenware, i. 232.

blue, man Cambridge, analyzed, i. 242.—contraction of, in burning into brick, i. 243.—ufe of, in promoting vegetation, i. 244.

Cost, made at Newcastle and Cambridge compared, i. 262.—becomes denser by a longer exposure to the sire, but loses thereby much of its weight, i. 263.—recommended for the making of pig-iron, i. 264.—whether there is not a definite weight to which a ton of coal should be reduced, in being converted into coak, in order to be applied to the greatest advantage to the sluxing of iron ore, ibid.—patent for the preparation of, granted lately in France, ii. 403.

iron ore, ibid. — patent for the preparation in France, ii. 493.

Coaleries on fire in Scotland and in Staffordshire, i. 78.

Cabale, ores of Hesse, produce an income of 14000s. 2 year, and formerly employed in mending the roads, i. 18.

Colorbae, what, used in Paris for polishing plate glass, i. 82.

Cold, greatest ever known produced by dissolving snow in acid of nitre, i. 101.—production, by evaporation mentioned by various writers, i. 323.—produced by the solution of falts, ibid.—the greatest degree produced by the solution of salt always the same, whatever be the temperature of the water previous to solution, i. 325.—quantity produced by different falts does not depend on any general principles hitherto discovered, i. 326.

Colors, excellency of referred to the goodness of the alkali used in dying, i. 116.

Compass, mariners, according to Busson known to the ancients, ii. 459.

Concentration, what, i. 28.

Concentration, what, i. 28.

Copper Waters, copper obtained from, by means of iron, i. 91—
reason of the process, i. 92.

Copper Stones, what, i. 75.

Copper first coined at Rome by Servius Tullius, and the only money as a cubic foor of different form, ii. 436.—density much increased by hammering, ibid—malleability not the only criterion of its goodness, ii. 440—vessels of it kept clean may be used with safety ii. 464.—art of silvering of, known to the Romans, ii. 485.—how plated with silver, ii. 493.—thinness of the silver on plated copper, ibid.—plating with the hinted at, ii. 494.—Art of plating with silver when and by whom first practiced in England, ibid.—finest fort from Japan, ii. 500.—houses covered with, in Sweden, ii. 535.—weight of, an a covering for houses, compared with that of lead, flate and tile, ii. 536.

Creven,

Craven.

Craven, in Yorkshire, lead ore rich in filver there, i. 390.

Capellation - capel, what, i. 395.

da furnace, when introduced into Derbyshire, i. 375,-called by foreigners the English furnace, ibid.—its advantages i. 376.
—method of smelting in, described, ibid. tanting and so well got

Denfity, mean, of the earth to that of water as 41 to 1, i. 79 .conjecture concerning the cause of the great mean density of the earth, ibid. anconicate water works

Depblegmation, what, i. 28.

Derbysbire firata, thicknesses of, i. 211.

Detonation of nitre, what, i. 199. . Legace and ching printing, do.

Dew falling, collected by some bodies and not by other, i. 298 .of great use to the vegetation of trees in Egypt, i. 299.

Diamonds wholly volatile in a degree of heat in which rubies were

unchanged, i. 22.

Dioscorides, physician to Cleopatra, knew how to sublime quicksilver, and to collect an oil from boiling pitch, i. 26.

Discletion, in the 3d century, ordered all chemical books to be burned. i. 6.

Distillation, what, i. 24. - various kinds of, i. 25 .- when introduced into Europe, i. 26 .- not known to Dioscorides, i. 27 .known to Geber the Arab, and to Zofimus of Panopolis, ibio

Dutch faid to extract filver from lead, which cannot in England be refined to advantage, i. 396.

Earth, argillaceous, how diftinguished from other earths, i. 230.

Earth, argillaceous, how diffinguished from other earths, i. 230.

Earth, calcareous, whence so denominated, i. 199.—different forts of, burned to lime, i. 200.—a definite degree of heat requisite to convert any one fort of, into the best lime it will afford, i. 201—220.—mixed with clay easily vitrished, i. 203.—weight of a cubic foot of 12 sorm, i. 204.—quantity of lime obtained from each of the forts, i. 205.—and from 12 other forts, i. 206.—medium weight of a bushel of chalk before and after calcination, i. 207.—recovers in some instances, by exposure to the air, the whole of the weight lost by calcination, i. 217.—not altered in its dimensions by calcination, i. 221.—loss of weight sustained by various sorts of, by solution in an acid, i. 224.—weight lost by solution nearly equal to that lost by calcination, i. 227.—the substance which is lost a species of air, ibid.—heavier than common air in the proportion of 3 to 2, but contained in the atmosphere, ibid.—whether water is contained in pure calcareous earth? i. 229.—ii. 420.

Earth, Fuller's, exportation of, prohibited, ii. 445.

Earth, Fuller's, exportation of, prohibited, ii. 445.

Earth, globe, its mean density, i. 79. — internal heat of 48°, 1. 166.

i. 166 .- quantity of water evaporated from a definite part of its

furface, i. 293.

Edinburgh, mean heat of the springs there, i. 345.

Egyptians skilled in making coloured glass, in metallurgy, in dying leather and linen, in engraving upon precious stones, i. 6. — of the four periods of learning mentioned by Pliny the Egyptian the first — books burned by the order of Diocletian, lest the Egyptians should learn the art of making gold, ibid. — knew the method of refining gold by lead, i. 393.

Elements, chemical, what, 1. 39.

Elements, chemical, what, i. 39.

Elizabeth, Queen, wife policy of, in promoting the knowledge of metallurgy, i. 12.—ii. 441.

Enamel and china painting, colours for, how made, i. 392.

Ephefus, temple of, built on charred piles, i. 292.

Ether, what, degree of cold produced by evaporation of, i. 319.

Evaporation not simply owing to heat, promoted by dry winds, proportional to the surface of the suid, i. 23.—best dimensions of vessels fitted for the evaporation of sluids not yet ascertained by experiment, i. 24.—cold produced by, i. 318.—degree produced depends on the state of the atmosphere, i. 319.—method of cooling liquors by, i. 320—322—ice produced by, in the East Indies, i. 321.

Exportation of iron, copper, brass, &c. anciently prohibited, ii, 443.

Fens in Cambridgeshire more unwholsome in dry than in wet summers, i. 295.

Filtration, what, i. 37.

Five, dilatation of the dimensions of bodies accasioned by it, the most certain criterion of its presence and agency, i. 59.—its mode of action attempted to be explained on Newton's principles of mutual attraction, i. 61.—nothing distinct from the parts of bodies put into motion by various causes, i. 62.—Borthave's opinion concerning it, ibid.—Buler's opinion, i. 63.—elementary, what, i. 65.—fixed or phlogiston, what, ibid.—subterraneous, cause of volcanos and earthquakes, i. 71.—origin of, illustrated by experiment, i. 72.—generated spontaneously by the fermenation of vegetable, animal, mineral substances, i. 74.

Fixity, what, i. 22.—not proportional to the hardness of bodies, ibid.

Flint enters into the composition of stoneware, i. 233—formerly

Flint enters into the composition of stoneware, 1. 233 — formerly ground with granite, now with chert, ibid. — subject to decay weight of a cubic foot of black and white, ii. 438,

Franklin, Dr. illustrates the principle of water being soluble in air,

eeg leetend dentutes - . qu'il pulant anne en péole Arens Gall-

"G

Gall-nuts, how formed, i. 94. - ferviceable in discovering minute portions of iron in chalybeate waters, i. ibid.

Geber, called the father of chemistry, i. 8. - uncertainty as to the age in which he lived, ibid.

Geneva lake, temperature of, at different depths, 1. 186.

Gilding in Or moulu, what, ii. 496.

Glass, coloured, making of, known to the Egyptians, i. 4. - how coloured, 1. 392. — plate made in Picardy, i. 82. — and in Lancashire, ibid. — conjecture concerning a more expeditious method of polishing, i. 83.—might be made from Westmoreland slate, &c. ii. 538.—fossil existence of, probable, ii. 539.

Glass-wort, all the forts of, called kali, i. 45.

Glaze, black, used at Nottingham, i. 236.

Gogmagog-Hills, near Cambridge, hear of the well there, i. 344.

Golden Calf, probably filed or stamped into a fine dust, i. 5.

Gold used in commerce 1100 years before the foundation of Rome, i. 369.—standard, what, i. 398.—tenuity of, on gilt wire, ii. 495 dissolved by quickfilver, ii. 496.—separated by quickfilver

from earths and ftones, ii. 497.

Granite of Cornwall, thought to resemble the Chinese petunse, it 237.—of Aberdeen, weight of a cubic foot of less durable than Guernsey pebble when used for paving, ii. 540.—found in detached pieces in the marl pits of Cheshire, on the Welch coast, in Westmoreland, &c. ii. 545.—primitive mountains composed of, ibid.—many varieties of, found in Great Britain, ii. 546. -fome forts subject to decomposition by the action of the atmosphere, ibid.

Guiacum, coal of, takes fire by simple exposure to the air. i. 291.

Gun-metal, of what composed in different parts of Europe in the last century, ii. 462.—how made now at Woolwich, ii. 443.—injured by lead, ibid.

Gans, brass, weight of those now in use as cast at Woolwich, ibid.

Gunpowder made in England in 1417, i. 109.—history of its dif-

covery, i. 126. known to Roger Bacon, i. 129. and to the Chinese above 2000 years ago, i. 131.—of great use in mining, ibid.—first used in that way in Germany, ibid.—that application of it, probably, introduced into England by prince Rupert, i. 132.—and first at Ecton in Staffordshire, i. 131.—how made, i. 134.—charcoal of, soft wood not preferable to that of the hardest for the making of, i. 135 .- made withour fulphur, inferior in strength to that which is made with, i. 137 .- quality of, injured by moisture, i. 138. proportion of ingredie the gunpowders of different countries, i. 140. problem of, determining the best possible proportions not folved, i. 141. caution to be used in drying gunpowder lest the sulphur should

be evaporated, as it all may be evaporated without an explosion taking place, ibid.—explosion takes place in the 600th degree of Fahrenheit's ther. i. 142.—effect of moisture on, ibid.—keeping it in glazed earthen vessels, or in vessels of tin or copper hinted at, i. 143.—method of analyzing ibid.—exemplified in some forts, i. 145.—bad effect of sea salt when mixed with salt petre, in the composition of gunpowder, i. 146.

Gypsum, what, i. 244.—used by the ancients for cielings, medallions, cornices, &c. i. 245,—Ethiopians covered their dead with, ii. 530.

11,539

Haller, baron, could fmell the perspiration of old people at the dis-

tance of ten yards, i. 307.

Halley, his opinion of the origin of the faltness of the fea, i. 170. tion of water in air, i. 316. quoted on the subject of the solu-

Hamilton, Dr. his effays referred to, i. 318.

Hamilton, Dr. his effays referred to, i. 318.

Hamilton, Conjecture concerning the use he made of vinegar in opening his way through the Alpine rocks, i. 133.

Harrowgate, heat of some springs there, i. 345.——sulphur well there, controversy about its containing sulphur, i. 346.——its sulphureous water imitated by dissolving lead ore, or black-jack, in acid of vitriol, i. 347.——and by calcined sea wrack 1. 349.

Heat, different degrees of, used in chemical operations, i. 29.i. 59.—not produced by the rays of the fun collected into a focus in a medium of an uniform density, i. 61.—excited by mixing acids with oils and with water, i. 100.—doubtful whether it be ever excited by mixture of fluids whose bulks are not changed,

i. 101.

Heberden, Dr. the first person who observed that much more rain falls into a rain-gage situated near the surface of the earth, than into one of the same dimensions a few yards above it, i. 300.

Henckel, the first person in Europe who procured zinc from calamine,

Herculaneum, the charcoal formed there by the lava which deftroyed the city still entire, i. 202.—vessels of bronze covered with silver

dug there, ii. 484.

Lersdatus mentions a curious method in which the Ethiopians preferved their dead, ii. 539.

Lermetic art, chemistry so called from Hermes supposed to be Mizraim, grandson of Noah, i. 5.

Hermetically sealed, what, ii. 517.
Higgins. Dr. has made white copper from English materials, ii. 459. elegand magical and that represent gold at Land at Hippocrates,

Hippocrates, has remarked that water is diminished in quantity by being frozen, i. 339.

History, antediluvian, contained only in the first fix chapters of Genefis, i. 2 .- of chemistry, i. 4 .- authors who have treated of

Holywell, method there in use of extracting filver from lead,

, States of, method used by, for stopping an epidemical diseafe, i. 296.

Hooke, Dr. his opinion concerning all land being raised out of the sea by earthquakes, i. 71.—thought that air supported fire by dissolving the inflammable principle of bodies, i. 289,—thought that the parts of water had different degrees of volatility, i. 336.

Hunter, Dr. his georgical effays referred to, i. 318. Huntsman, famous for casting steel at Shesield, ii. 470.

Iceland produced by volcanos, i. 71.

Ice, method of making, in the East Indies, i. 321 .- may be made in the middle of fummer, i. 326.—a fort of white land, or transparent stone, i. 338.—used as stone by the Russians in 1739.

ibid.—loses of its weight by exposure to the air, i. 339.—but not in vacuo, ibid.—quantity of, on the surface of the earth supposed to increase annually, i. 342.—limit to this increase,

Magrace, Modernes Teed

i. 343.

India, brafs made there in remote ages, ii. 455.

Iron, known before the deluge, i. 3.—melting of, known to the Hottentots, ibid.—foftened by vitriolic and by fea water. i. 85.—

tentots, ibid.—foftened by vitriolic and by fea water. i. 85. changed into a kind of stone, i. 86.—improved by being buried in the earth, i. 85.—ii. 439.—apparent transmutation of, into copper explained, i. 90.—From Lancashire ore as tough as Spanish iron, ii. 440.—sew forts of, fit for making steel, ibid.—use of in war forbidden the Romans by Porsenna, ii. 458.—great loss of, when manufactured, ii. 487.—used for covering of houses in Norway, ibid.—and in Rusha, ii. 535.

Bishop of Seville, quoted, ii. 450. Ter distinguished from cannel coal, i, 277. - weight of a cubic foot

Jews, whether they knew the art of tinning copper vellels, ii. 483. come in to Kert application

Kali, Arabic name for glass-wort, or marsh samphire, i. 44. Kebble, weight of a cubic foot of, i. 19. Kelp alhes made in various parts of Great Britain, i. 46 .- analyzed,

## IND EXX.

sbid.—contain less fixed alkali than is contained in Spanish ba-

Kendale, price of Westmoreland slate there, ii. 534.

Kunckel, his processes for enamelling may be relied on, i. 14.

Lapis obfidianus, what, ii. 539 Lapis specularis, what, i. 246.—used by the Romans for protecting their fruit trees, ibid.—esteemed by Agricola a fort of plaster

Lapis specularis, what, i. 246.—used by the Romans for protecting their fruit trees, ibid.—esteemed by Agricola a fort of plaster stone, i. 247.

Lande, M. de La. too hastily concludes that the Romans did not know the art of tinning copper vessels, ii. 484.

Llandes M. de La. too hastily concludes that the Romans did not know the art of tinning copper vessels, ii. 484.

Landes, Dr. Isaac, probably the second person in Europe who procured zinc from calamine, ii. 428.

Lead in a strong fire burns like rotten wood, i. 67.—changed by burning into ashes and the ashes into glass, i. 70.—the ashes or glass being melted with charcoal, or any substance containing phlogiston, becomes lead, ibid.—melted exhibits a succession of colours, i. 365.—property of exhibiting colours destroyed by the admixture of small portions of fin and zinc, but not by bistanuth or silver, ibid.—contained in a large proportion in the slags of the melting houses, i. 382.—quantity of, annually smelted in the languagem was refined for silver, there would be an annual saving of ainety thousand ounces of silver, ibid.—equantity of lead lost by extracting the silver, i. 396.—weight of a cubic foot of ragious sons of, i. 407.—quantity of silver contained in these sons, i. 408—heaviest contains least silver, ibid.—weight of a square sons of, i. 407.—quantity of silver contained in these sons of sons of, i. 407.—milled more uniform in thickness than cast, ii. 535.—inferior as a covering tast but a sew years in the torrid zone, ii. 544.—milled more uniform in thickness than cast, ii. 535.—inferior as a covering to well understood in France, i. 401.—weighs more than the lead from which it is made, i. 402.—the increase of weight owing to the sir which is absorbed by it, ibid.—when reduced into lead does not weigh so much as the lead used in making it, i. 403.—made from a mixture of ore lead and slag lead, ii. 404.—a portion of lead remains in making red lead, which cannot easily be changed into red lead, i. 405.—this portion does not contain any extraordin

Lead, white, or ceruffe, how made, i. 408.—our method of making, the fame as that of the ancients, i. 409.—Roman ladies used it as a colmetic, use of it centured by St. Jerome, there in Me to wathin portrol Great Britain, L & . - analysed,

#### I N D E X

ibid. used to adulterate wines, i. 411, method of detect-

ing the adulteration, i. 412.

Line, quantity of, obtained from various forts of calcareous earths, i. 205 .- from the fame fort of earth calcined for differen lengths of time, i. 210.—increase of weight acquired by various forts of, when exposed to the air, i. 215.—the substance acquired not evaporable by the heat of summer, i. 216.

Litharge, what, i. 394 - quantity of, obtained from a ton of

lead, i. 396.

London, mean heat of springs there, i. 345.

Looking-glasses, how silvered, ii. 504.—inquiry into the time when the art of silvering them was discovered, ibid.—men

employed in filvering become paralytic, ii. 504.

Luc. M. de, of opinion that the Glaciers of the Alps annually increase, i. 342. — heat of boiling water ascertained by,

Lully, Raymund, born at Majorca, introduced the notion of an unito least table of a versal remedy, i. 9.

Manganese, used in giving a black glaze to earthen-ware, i. 236.

Marble, black Derbyshire, weight of a cubic foot of, i. 212.—

weight of lime from a ton of, ibid.— Sienna, statuary, &c. specific gravities of, and quantities of lime from given weights of, i. 205.

Marcaste, what, i. 76.

Marcafite, what, i. 75. , what, i. 241. method of analyzing, i. 242. various in quality in the fame pit, ibid.

The reds man Spans

three new ones lately discovered, i. 18 .- composed of

Metals, three new ones lately discovered, i. 18.—composed of earth and phlogiston, i. 69.—six known to Moses, i. 368.

—distinguished from semi-metals, thid.

Metallurgy, known to the ante-diluvians, i. 3.—and to the Hottentots, ibid.—and to the Egyptiam before the time of Moses, i. 8.—no books on, lest by the ancients, i. 12.—improvement of, important to this country and best accomplished by the establishment of a chemical academy, i. 19.

Middleton, Sir Hugh, cleared large sums from the lead mines, in Cardiganshire, and enabled thereby to undertake the bringing the new river from Ware to London, i. 389.

g the new river from Ware to London, i. 389.

d, used near a century ago for sheathing of thips,

ii. 488. Mining, gunpowder of use in, i. 131. - splitting rocks by the fwelling of wet wooden wedges, an art of the miners, ibid.—by wooden fires an ancient and modern practice, i. 132.

Modern, a remarkable rock in the ducky of, i. 277.

Mosey, coined of pewter by James II. ii. 466.—and by the American Congress, ibid.

Moses

# IN NA DO EN X

Mose did not probably either calcine the golden calf or render it foluble in water, i. 5.

mberg, brafs made there, fitteft for mulical instruments,

Nuremberg, brass made there, fittest for musical instruments, ii, 434.

Oat, dry, quantity of assessment from the combustion of, and quantity of saline matter from the asses, i. 51.—taspings of heart of, give a fine blue colour with a folution of green vitriol, i. 95.—products from the distillation of 96 ounces of, i. 257.—inflammable air from, i. 268—contains one third of its weight of air, i. 259.—great loss of weight suffained by, in a sew days when expused to the air, i. 281.—weight of charcoal from the grains of, i. 283.

Oil of turpentine distilled with acid of sulphur yields sulphur, ii. 69.—mixed with acid of nitre takes fire, i. 99.—Borrichius the first observer of the phenomenon; authors referred to who have prosecuted the inquiry, ibid.

Oil from the distillation of pia coal of two forts, i. 255.—quantity of, separable from a given weight of the coal, ibid.—from the distillation of various woods of the same nature as that from coal, i. 257.—faving of, recommended to the burners of charcoal, i. 267.

Onion germinating in the open air, are increased in bulk but dimi-

coal, i. 257.— faving or, recommended to the contract coal, i. 267.

nites germinating in the open air, are increased in bulk but diminished in weight, i. 311.

schence, beats, cast at Woolwich, ii. 463.

c., land, purchasing by measure liable to exception, i. 351—
specimens of, equally free from spar differ greatly in weight, ibid.—specific gravity of different forts ascertained, i. 352.—does not yield its lead as soon as it is melted, i. 354—yields lead without the addition of phlogiston by being kept in suson for a long time, i. 355.—does not yield sulphur by distillation, ibid.

# I N 3D OR VX

ibid.— may be whally sublimed by a firong heat, i. 356.—
cannot be decomposed in close vessels, i. 357.— sublimed referables common are in union and waiting as a. of recommended, i. 363 finefice, a when smelted by pit-coul, i. 367 inted at, i. 370.

ming the existence of the m

defwick, a lead mine rich in filver there, it is of making in the roads of Lancal

t, his account of the quantity of filver made at Holywell,

Pennerth limestone, its specific gravity and peculiar quality,

Percioal Di. Maellays referred to, L. 301-11111113; in sel

ver without a bellows, probably after the man dy practifed in Macedonis, and in Derbythin a pulithed lava for a speculum, ii, 460.

what it is made, of 3 forts, ir. 478.——weight of a to de each fort, ii. 479——within for making a fill metal, ibid.——affectation of mystery in the er of making, ibid.

Vos. II.

Phlogiflen,

Phlopiflor, what, i. 66.—identity of, ascertained, i. 70.—probably an elastic inflammable suid, i. 287.

Piscoal, Newcastle, Halle, Alais distilled, i. 254.—watery liquor separable therefrom contains both an acid and a volatile alkali, i. 255.—two sorts of oil procured from by distillation, ibid.—contains a third of its weight of air, i. 256.—lose 9 parts in 20 of its weight in being converted into coak, i. 264.—pitch and tar made from, by Beccher in Charles IId's time, ibid.—and more recently at Liege and at Broseley, i. 265.—average quantity of, annually imported into London, i. 269.—weight of a Newcastle and of a London chalder of, i. 270.—weight of a cubic soc of various sorts of, ibid.—medium weight of a bushel of, i. 272.—burning of, introduced into London in 1305, ibid.—prejudice against the use of, ill sounded, i. 273.—tar distilled from, in France, ii. 492.—method of distilling brought to great parsection by the Earl of Dundonald, ii. 493.—rounded by water, ii. 544.

Pitch, mineral, what, i. 274.

Platine, what, i. 246.—quantity of, raised annually near Newarth, i. 251.—composed of calcareous earth united to the acid of vitriol, ibid.—foliuble in water, i. 247.

Platine, a favorath metal, lately discovered, i. 368.

Porcelase, how made, i. 237.—Dresden as unvitrisable as the Assistic, i. 239.—reason for effecting that fort most which is least vitrisable, i. 240.—best method of encouraging manuscourse of in Europe, ibid.

Porsense did not allow the Romans the use of iron in war, ii. 458.

nufactories of, in Europe, ibid.

Perfense did not allow the Romana the use of iron in war, ii. 458.

Pot-ass, what, i. 52.—quantity of contained in wood-asses i. 52.—

making of, encouraged, i. 52.—various hints relative thereto, i. 98.

Pot-metal, what, how made by the ancients, ii. 466.—medals made of, after the age of Sep. Severus, ii. 467.

Presibilitation explained, i. 99.

Precipitation explained, i. 90.

Pre-emption of ores, right of, should be abolished, i. 388.

Prieftley, Dr. his experiments referred to, i. 288, 230, 337, 413,

Printelley, Dr. me capable
ii, 528.

Printelley, bishop of Adrametum, quoted, ii, 450.

Putty, what, i. 67.

Pyrites, what, i. 74.——found amongst pit-coal, i. 76.—
heaps of, take fire spontaneously, ibid.——land abounding with, has taken fire after rain, i. 77.——might be distilled for sulphur; green vitriol made from, i. 382.

Quartz, weight of a cubic foot of, ii. 544.—two pieces rub-bed together give a phosphoric light; Bristol stone purest fort of

## I N D E X

of, ibid. fubject to decay; constitutes fands of various forts, ibid.

Quickfilver, reduced to the flate of a malleable metal both by natural and artificial cold, i. 101, &c.—evaporable in vacuo, i. 315.—transpirable through the pores of the skin, ii. 406.—dissolves gold, ibid.—use of in the gold and filver mines of America, ii. 497.—no mines of, in England, ibid.—nines of, in Spain, Hungary, America, ibid.—how to be dif-covered in any mineral, ii. 499.

Rain, different quantities which fall on equal spaces situated upon or at a few yards above the surface of the earth, i. 300.—phe-

or at a few yards above the furface of the earth, i. 300—phenomenon attempted to be accounted for, i. 301, 313.

Redification, what, i. 28.

Reduction, what, i. 70.

Retort, Receiver, what, i. 25.

Rock falt, at Northwich, in Poland, in Spain, i. 150.—quantity of, foluble in a definite weight of water, ibid.—ufe of, in strengthening sea water or weak brine, i. 154.

Romans had an imperfect knowledge of Britain in the time of Cicero, i. 385.—probably taught the Britains the art of extracting silver from lead, i. 386.—knew our method of making brass, ii. 451.—composition of statuary metal used by them, ii. 462.—composition of their pot-metal, ii. 466.—knew our method of tinning copper, ii. 484.—used glass for their windows, ii. 506. 11. 506.

Roy, Mr. Le, an ingenious experiment of his illustrating the folution

of water in air, i. 316. Royal Society, origin of, i. 13.

Wat to it does a province ?.

Saccbarum Saturni, what, i. 411—wine adulterated by, ibid.
—method of discovering the adulteration, i. 412.

Saline substance, what, i. 42.—of three forts, acid, alkaline, neutral, i. 43.—tables of, i. 56.—composition of, i. 58.

Salts, all the different forts assume in crystallizing their own particu-

hivery common falt how made, i. 158.—fecret of the Dutch in purifying, ibid.—refuse used as a manure, i. 161.—applied as a manure, in too large quantities produces then lity, i. 162.—whether daily generated, i. 175.—probability of descenageing it by putrefaction, i. 268.

It is a manufacturing of, formerly much attended to in England, i. 110.—authors reserved to who treat of the manner of making it, i. 112.—dearness of labour and of wood ashes, principal reasons of the failure of attempts to establish manufactories of falt-petre in England, i. 113.—wood ashes not necessary in all cases to the making of falt-petre, ibid.—falt-petre or falt petras derived from the faline shoots met with on old walls, i. 115.—a lump of, found in digging gravel near Bury St. Edmund, i. 114.—mineral alkali said to be spontaneously changed into falt-petre, i. 116.—not always accompanied with sea sait in the earths where it is generated, ibid.—difficult to decide the question how it is generated, i. 117.—never produced except in substances which have undergone a putrefactive sementation, i. 118.—its production connected with that of volatile alkali, i. 118.—its production connected with that of volatile alkali, i. 118.—its production connected with that of volatile alkali, i. 119.—and in Spuis, i. 124.—quantity made in Prance, i. 125.—vise palicy of the French and inadvertence of the English noticed, idid.—the Pope and dake of Bavaria amongs the first grinces in Europe who encouraged the making of falt-petre, i. 128.—its production connected with that of prance, i. 125.—wise palicy of the French and inadvertence of the English noticed, idid.—the Pope and dake of Bavaria amongs the first grinces in Europe who encouraged the making of falt-petre, i. 128. petre, i. 116.-

Steel, cast, porous when not in a strong fusion, ii. 470 .- casting of, when and by whom introduced at Sheffield, ibid.-price of casting, of drawing into the shape of razors, &c. ibid.—runs from the hammer like sand in a welding heat, ii. 471.

Stone, feveral forts of diminished in density and decomposed by long exposure to the air, ii. 437 .- weight of a cubic foot of many forts,

ii. 611.

Strabo describes an ore of zinc, ii. 452 .- and the formation of the

Rhenish mill-stone ii . 546.

Sublimation, what, 1. 24 .- of quickfilver known to Dioscorides, i. 26. Sulphur composed of an acid and phlogiston, i. 66 .- proportion of thefe parts - formed by distilling the acid of sulphur with charcoal -and with spirits of wine-and with oil of turpentine-and by pouring the acid on melted lead, i. 68,-fublimed from Harrowgate water, i. 346 .- contained in the lead ore of Derbyshire, i. 360.—obtained from the roasting of copper ore, and might be obtained from the pyrites which is found amongst pit-coal, i. 382. Sweat, evaporation of, cools the body, i. 322.

Sweden, use of copper vessels abolished in the navy and army of, 11. 471.

Table, of the weight of a cubic foot of cawk, &c. i. 19.-of falts in general, i. 56 .- of neutral falts with alkaline bases, i. 57 .- of the quantity of falt-petre imported into England in 7 years, i. 124. —and of the quantity exported, ibid.—of the proportions in which the materials for making gunpowder are used in different which the materials for making gunpowder are used in different countries, i. 140.—of the temperature of the lake of Geneva at different depths, i. 186.—of the weight of a cubic foot of various calcareous stones, i. 204.—of the loss of weight sustained by calcareous stones during calcination, i. 205.—of the thicknesses of the strata in Derbyshire, i. 111.—of the increase of weight which different limes acquire by exposure to the air, i. 215.—of the loss of weight sustained by different calcareous substances during their solution in an acid, i. 224—226.—of the relative weights of china, shint ware, yellow ware, i. 241.—of the products obtained by distillation from different sorts of pit-coal, i. 254.—and of the different sorts of wood, i. 257.—of the quantity of pit-coal annually imported into London, i. 269.—of the weight of a cubic foot of different sorts of wood, i. 280.—of the weight of charcoal from different sorts of wood, i. 280.—of the weight of charcoal from different forts of wood, i. 283.—of the heat of boiling water, i. 333.—of the weight wood, i. 280.—of the weight of charcost from different forts of wood, i. 283.—of the heat of boiling water, i. 333.—of the weight of a cubic foot of different lead ores, i. 351.—and of spars, i. 353.—and of various slags, i. 384.—and of toadstone, &c. i. 385.—of the quantity of silver extracted from lead in Wales, i. 395.—of the weight of different forts of lead, i. 407.—of the silver contained in the same, i. 408.—of zinc contained in different calamines, ii. 424.—of the weight of different pieces of brass ord nance,

nance, ii. 463 .- of the weight of a cubic foot of various mixtures of tin and lead, ii. 477.—of pewters, ii. 479.—of the weight of a cubic foot of various forts of Westmoreland slate, ii. 530. of the quantity of copper, flate, &c. requifite to cover 42 fquare yards of roof, ii. 536.—of the weight of a cubic foot of feveral forts of stones, ii. 611.

Tar, method of making of, i. 265 .- made from pit coal at Liege, i. 266 .- making of, recommended to the burners of coak, ibid .and of charcoal, i. 267.—made by the earl of Dundonald, and in

France, ii. 493-

Tartar, what, i. 53-falt of, what, ibid.—cream of, what, i. 53.oil of delignium, what, ibid .- quantity of water attracted from the air by, i. 310.

Tell, what, i. 394-Tile, common, imbibes much water, ii. 531.—great weight of, when

applied as a covering for houses, ii. 536.

Tin, a small portion of destroys the colours of melted lead, i. 364. principal ingredient in the mixture for tinning copper vessels, ii. 472.—used alone for that purpose, ibid.—pure English contains no arfenic, ii. 473 .- pure use of not unwholesome, ii. 474 .- purity of, how ascertained in Cornwall, ii. 475.—block of, what, ibid.—in Holland all forts of, fold as English tin, ibid.—weight of, ii. 476.—in fetting after fulion is brittle, ibid,—grain, what, ii. 477, 469.—mixed with lead, ii. 477.—English faid by foreigners to be a mixed metal, ii. 480.—melts with less heat than any simple metallic substance except quickfilver, ii. 486.

Tinning of copper, thickness of the tin on the copper, ii 483.—improved method of, lately discovered at Paris, ibid.—art of, known

to the Romans, ii. 484.

Tinning of iron, how performed, ii. 488.—whether iron might not be filvered in the same way, ii. 489.—quantity of tin used in covering a definite surface of iron, and the thickness of the tin estimated,

ii. 490.—history of the tin plate manufactory, ii. 491.

coadstone, Derbyshire, thickness of its stratum, i. 211.—resembles some forts of Vesuvian lava in hardness, colour, and weight, i. 384.

—may be melted into a black glass, is reduced by the air into mould, weight of a compact and of a decaying piece, ibid.—stones resembling toadstone found in various places, ii. 610.

Transmutation of metals, uncertain when the notion was introduced, i. 7.—never proved to be an impossible problem, ibid.—practice of, prohibited by pope John in 1316.—and by act of Parliament, Hen. IV. i. 9 .- allowed by letters patent, 35 Hen. VI. i. 10.

Tulenag, the Indian name for zinc, ii. 426.

275

Valentine, Bafile, greatly contributed to the introducing antimony into the practice of physic, i. 9. Vapour,

Vapour, rising from the ground in dry weather, quantity of, estimated, i. 293.—is attracted by glass, but not by filver, &c. i. 297.

Vegetation, improved by small quantities of common falt, i. 163.—
influenced by the quantity of water raised from the earth i. 298.—
light and air requisite for, ii. 527.—water converted into earth by,

light and air requilite for, in. 527.—which is 529.

Versilite, what, ii. 500.

Virriel, green, what, ii. 81.—composed, ibid.—decomposed, ii. 82.—phlegm, spirit, oil, glacial oil of, ii. 84.—native, how formed, ii. 84.—met with in the cannel coal-pits near Wigan, abid.—blue, white, what, ii. 86.—green, how made at Departord, Wigan, &c. ii. 87.—price of, sunh, ibid.—history of its being made in England, ii. 88.—manner of discovering whether it contains copper, ibid.—may be made after copper is precipitated by iron, ii. 93.

Volcanos, distribled sinc from black-jack in 1738, ii. 18.

Volcanos, islands produced by, ii. 72.

Volcanos, islands produced by, ii. 72.

eight of falt, it 172 miver, contains about to of its eight of falt, it 172 miver, contains about one four thousandth art of its weight of falt; it 172 miver itself from falts, carthy, to by congelation, it to the great quantity of evaporated from the countries are the second in th

ras before, ibid.

Worts

Vort, fermenting, heat of the same as of an animal body, i. 308 .-

Zinc distilled from black-jack, i. 18,—mixed with melted lead hinders the lead from exhibiting colours, i. 369.—manufactory of, established at Bristol by Mr. Champion in 1743, ii. 429.—quantity annually made there, ibid,—method of making, ii. 430.—sent to Birmingham under the name of spelter, ibid,—made at Gostar in Germany and in India, ibid—relative weight of Indian—German—English, ibid.—combustion of, use in fireworks, yields inflammable at by solution in acid of vitriol, ii. 431.—method of obtaining pure, ii. 432.—made by Mr. Emerson at Hennam, ibid,—melted with copper constitutes pinehbeck and other yellow metals, ibid.—best proportions ascertained, ibid.—a patent for making brass from zinc and copper, ii. 433.—recommended for covering copper, ii. 481.

Zosimus, in the 4th century, knew the art of distilling, i. 27.

Zwart, Kops, salt pas, i. 155.
